LIST OF ILLUSTRATIONS

Special Plates

	PAGE
...hiectasis, Congenital (R. V. Morlock and A. J. Scott Pinchin)	facing 789
...e Hygroma of Neck treated by Sodium Morrhuate (Gordon Harrower)	facing 161
...phragmatic Hernia (J. R. Crumbie and J. Stephens), inset between	22 and 23
...verticulum of the Duodenum (David Cromie) inset between 1034 and	1035
...verticulum of the Duodenum (Charles E. Salter) inset between	1034 and 1035
...sphagia, Vallecular (John E. G. McGibbon and J. H. Mather)	facing 1034
...lis Ab Igne (Allan Warner) ...	inset between 160 and 161
...brosarcoma of the Suprarenal Gland (Brennan S. Cran) ..	facing 1034
...e of both Bones of the Leg (E. N. Wardle) inset between 160 and	161
... of Spine, Treatment and Transportation (W. S. Haughton)	inset between 788 and 789
...ctures of Tibia, Compound, Treatment of (A. Simpson-Smith)	inset between 1034 and 1035
...usion Operations as Applied to the Hip-joint (G. R. Girdlestone)	inset between 788 and 789
...anglionectomy, First Thoracic, in Parkinson's Syndrome (Gordon Harrower and K. C. Ghosh)	facing 788
...gioma of the Spine (F. Strong Heaney and P. H. Whitaker)	inset between 788 and 789
...rt Disease, Radiology in (John Parkinson)	facing 612
...rt Disease, Radiology in (Peter Kerley)	inset between 612 and 613
...rpes Zoster Brachialis with Concurrent Varicelliform Eruption (F. A. E. Silcock)	facing 161
...ntestino-vesical Fistula (R. J. Willan)	facing 160
...ain Abscess following Tonsillectomy (F. T. Ranson and L. McGolrick)	inset between 1034 and 1035
...h Foot" (Harold Dodd)	facing 788
...a Deformans treated with Parathormone (G. H. Colt and A. Lyall)	inset between 22 and 23
...thorax, Chronic Bilateral Spontaneous (Joseph Lewis)	facing 789
...ets (John Pool McGowan)	facing 613
...thectomy in Anterior Poliomyelitis (E. D. Telford and J. S. B. Stopford)	facing 788
Syphilitic Spondylitis (A. Wilson Gill and A. D. Frazer) ..	facing 613
Tumours, Intracranial (W. E. Carnegie Dickson)	facing 1035
Ulcer, Chronic Perforating, of Foot (T. G. Illtyd James and Norman M. Matheson)	facing 23
Ulcers, Gastric, Multiple (A. Wilfrid Adams) ..	inset between 22 and 23
Volvulus of Pelvic Colon, Recurrent (D. Ligat and T. D. Overend)	facing 22
X-Ray Treatment of Malignant Disease of the Lung (Fl. Roberts)	facing 160

INDEX TO THE EPITOME FOR VOLUME II, 1933

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

Abderhalden test for pregnancy, 76
Abdominal inspection, direct, by cystoscope, 297
Abdominal masses, radio-diagnosis of, 459
Abortifacient (apiol) followed by polyneuritis, 18
Abortion, attempted, in ectopic pregnancy, 51
Abortion, causes and sequels of, 429
Abortion, febrile, treatment of, 128
ABRAHAMSEN, H.: Operations on the semilunar cartilage, 241
Abscess of abdominal wall in intestinal cancer, 66
Accessory sinuses and nose, ventilation of 47
Acetylcholine in secretory insufficiency of the stomach, 242
Achylia of endocrine origin, 152
Acne, juvenile polymorphous, 356
Acne, juvenile, radiotherapy of, 143
Adenoiditis, treatment of, 319
Adhesions, open, section of, 170
Adrenaline injections in cardiac syncope, 45
Agglutination test in Weil's disease, 219
Air, expired, temperature of, 256
ALAURENT, H: Primary ocular diphtheria in young children, 445
Alcohol and dextrose in puerperal pyaemia, 75
Alcohol injections in septicaemia, 16
Alcoholism, chronic, hepatic insufficiency in, 236
Alcoholism, clinical pathology of, 327
Alcoholism, emetine therapy in, 261
Algeria, osteomalacia in, 268
Alkali treatment of diabetic coma, 156
Allergy in certain oto-laryngological conditions, 106
Allergy and immunity in tuberculosis, 270
Allergy, tuberculous, in guinea-pigs, duration of, 234
ALLIEZ, J.: Suboccipital serotherapy in meningitis, 440
ALVAREZ, A: Juvenile polymorphous acne, 356
ALZAREZ, V. G.: Determination of bilirubinaemia, 328
Ambulatory treatment of haemorrhoids, 42
AMELINE, A.: Parathyroidectomy for ankylosing polyarthritis, 189
Amenorrhoea, endocrine factors in, 450
Amidopyrin in measles, 300
Amino acids in gastric and duodenal pain, 193
Ammonium chloride in scleroderma, 359
Amniotic fluid, quantitative determination of the, 179
Amoebiasis, intestinal, chronic, carbarsone in, 244
Ampulla of Vater, radiology of the, 482
Anaemia, hypochromic, of gastric and intestinal origin, 221
Anaemia, pernicious, liver therapy in, a seven years' review, 474
Anaemia, pernicious, and subacute combined degeneration, 387
Anaemia, treatment of, 88, 388
Anaesthesia, avertin, 424
Anaesthesia, ether, tetany during, 10
Anaesthesia, local, in ophthalmology, 403
Anaesthesia, lumbar, avoidance of complications in, 159
Anaesthesia, percaine, deaths from, 426
Anaesthetic, basal, sodium soneryl as a, 427
Anaesthetic for short operations (sodium evipan), 9
Anaesthetics, general and local, respiratory sensitization to, 160
Anaesthesia, modern aids to, 11
Anal fistula. *See* Fistula
Anaphylaxis and serum sickness, prevention of, 316
Aneurysm of aorta simulated by intrathoracic goitre, 206
Angina, agranulocytic, 60
Angina, electrocardiogram of dying heart in, 434
Angina: Haemagglutination reaction in sore throats (angina) with monocytosis, 14
Angina induced by general anoxaemia, 367
Angina pectoris induced by paroxysmal arrhythmia, 220
Angina pectoris, true and false, 62
Angioma, cavernous electrical treatment of, 188
Angiomatosis, cystic, of the retina, 195
Anoxaemia, general, angina induced by, 367
ANSELMINO, K. J.: Pancreatotropic effects of anterior pituitary extracts, 430
ANSPACH, B. M.: Endocrine factors in amenorrhoea and uterine bleeding, 450
Anti-streptococcal serum, use of, 336
Antitoxin intravenously in scarlet fever, 123
Antral surgery in bronchitic asthma, 466
Anxious states, treatment of, 461
Aorta, rupture of, in pregnancy, 325
Aorta, thoracic, dynamic dilatation of the, 329
Aortic embolus, operation for, 258
Aortitis, syphilitic, 455—Treatment of, 260
Apiol as an abortifacient followed by polyneuritis, 18
Appendicitis in pregnancy, 306
Appendicitis in the United States, deaths from, 415
Appendix in measles, histology of, 91
ARAGAO, H. B.: Serum-virus vaccination against yellow fever, 114
Arneth count, normal, in man, 251
ARONDEL P.: Fatal diabetes following scarlet fever, 38
Arrhythmia, complete, in infectious disease, 222
Arrhythmia, paroxysmal, inducing angina pectoris, 220
Arteriography in diagnosis, 416
Arteriography in vessel disease of the limbs, 422
Artery, splenic, "sympathectomy" of, 131
Arthritis, anaesthetic periarticular infiltrations in, 158
Aschheim-Zondek reaction in chorion-epithelioma, 29
Aschheim-Zondek test for pregnancy, 76, 267—A modification of, 77—In early pregnancy, 287
Aschheim-Zondek test. *See also* Prolan
ASLAN, A: Surgical treatment of endarteritis obliterans, 120
Asphyxia, mechanism and treatment of, 228
Asthma, bronchitic, antral surgery in, 466

Provisional Programme see "Supplement"

Including an Epitome of Current Medical Literature

WITH SUPPLEMENT

No. 3782 SATURDAY, JULY 1, 1933 Price 1/3

WHAT IS THE MEANING OF "HEALTH TEA"?

As a medical man you know the harm that is caused by the tannin found in ordinary teas. Now, in good China Tea there is at least 50% less tannin than in teas grown outside China. That is a fact of nature. In order to equal the claims of China Tea, the market is now being flooded with so-called "health" teas which claim to have been "made safe." There is no need to "make safe" The Doctor's China Tea—it **IS** safe, naturally and undeniably. Thousands of medical men have **proved** its claims to be ideal in cases of dyspepsia, other gastric troubles, and in cases of pregnancy. Would you care to make similar tests?

A free ½-lb. sample will gladly be sent to any medical man for the asking.

Managing Director.

THE DOCTORS CHINA TEA

Priced at 2/8, 3/2, 3/10, and a super quality at 4/4 per lb.

HARDEN BROS. & LINDSAY LTD. (Dept. 153), 30/4 Mincing Lane, E.C.3

CV3—95

Extracts from the B.M.J. concerning the occlusive dressing treatment of

IMPETIGO

Group I: Treatment by the Occlusive Dressing.

This consisted simply in the application of a piece of Elastoplast Bandage to the lesion whatever its stage of development. The lesion was not touched in any other way.

On the first visit the dressing was applied and the patient was told not to pull it off or wash it.

The evidence indicates that the advantage is strongly with the first method of treatment, *the period of invalidism being almost halved.*

Vide B.M.J., 13/5/33, pp. 823/4.

—— for the use of Elastoplast in Impetigo, having employed it both in School and in Child Welfare Clinics for *the past three years in some hundreds of cases with great satisfaction* to patients and resultant gratitude of my nursing staff.

I never now exclude from school for Impetigo.

The disease is rapidly disappearing from my schools.

Vide B.M.J., 3/6/33, p. 986.

The Digestive Tract

A Radiological Study of its Anatomy, Physiology, and Pathology

By ALFRED E. BARCLAY

Radiology is now recognised as the most important means of investigation. This method has, however, been singularly neglected in human anatomy and physiology, and it is clear that it must bring as drastic revision of pre-X-ray conceptions as in the diagnosis of pathological conditions. The author, one of the earliest workers on the subject, devotes half of the book to anatomy and physiology as viewed by the radiologist, and the second half to the diagnosis of pathological conditions.

Psychoanalysis and Medicine

A Study of the Wish to Fall Ill

By KARIN STEPHEN

DR ERNEST JONES, *President of the British Psycho-Analytical Society*, writes in his Preface: "Dr Karin Stephen has brought to the study of psychoanalysis an exceptionally critical mind which had previously displayed its capacity in a brilliant career in science and philosophy. In this book she essays the difficult task of conveying the elements of psychoanalytical knowledge to those versed in other fields. It would be hard to think of a better introduction."

,, XIII. Instruction in Medical Schools.
,, XIV. Birth Control Clinics.
,, XV. Municipal Clinics.
Plates I to X.

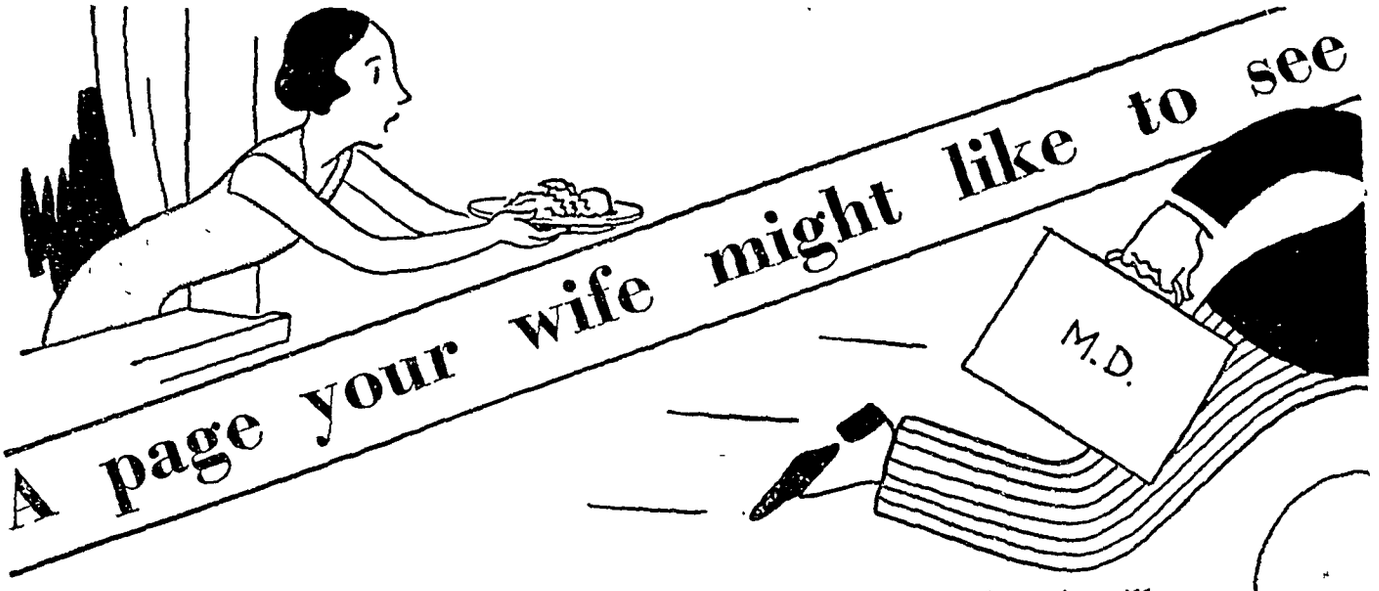
A few press opinions of the first edition of this world-famous book:

"It contains much information not procurable in any other volume and may be recommended for perusal by members of the medical profession."—*Medical Journal of Australia.*

"Dr. Stopes sets out with precision and no little literary grace the problem of contraception. . . Much of the evidence contained in the book is quite unobtainable elsewhere."—*The Lancet.*

"Some such book as this had to be written, and this is very well written."—SIR ARCHDALL REID in *Nature.*

"This problem will undoubtedly occupy a more prominent position in the future, and to those who wish to study it we can recommend this volume."—*Journal of State Medicine.*



"This highly important question cannot be studied completely and dispassionately without reference to her distinctly remarkable book."—*The Hospital and Health Review.*

"The book is unique and marks a new era in literature germane to this subject."—*The Medical Times.*

"The book is supremely important, and its author is one of the most important women of our time, for, almost single-handed, she is fighting a crusade which, successful or the reverse; cannot fail to have a momentous effect on our civilization."—*The Scottish Nation.*

Order from your Bookseller or direct from the Publishers:

G. P. PUTNAM'S SONS, 24, Bedford Street, LONDON, W.C.2

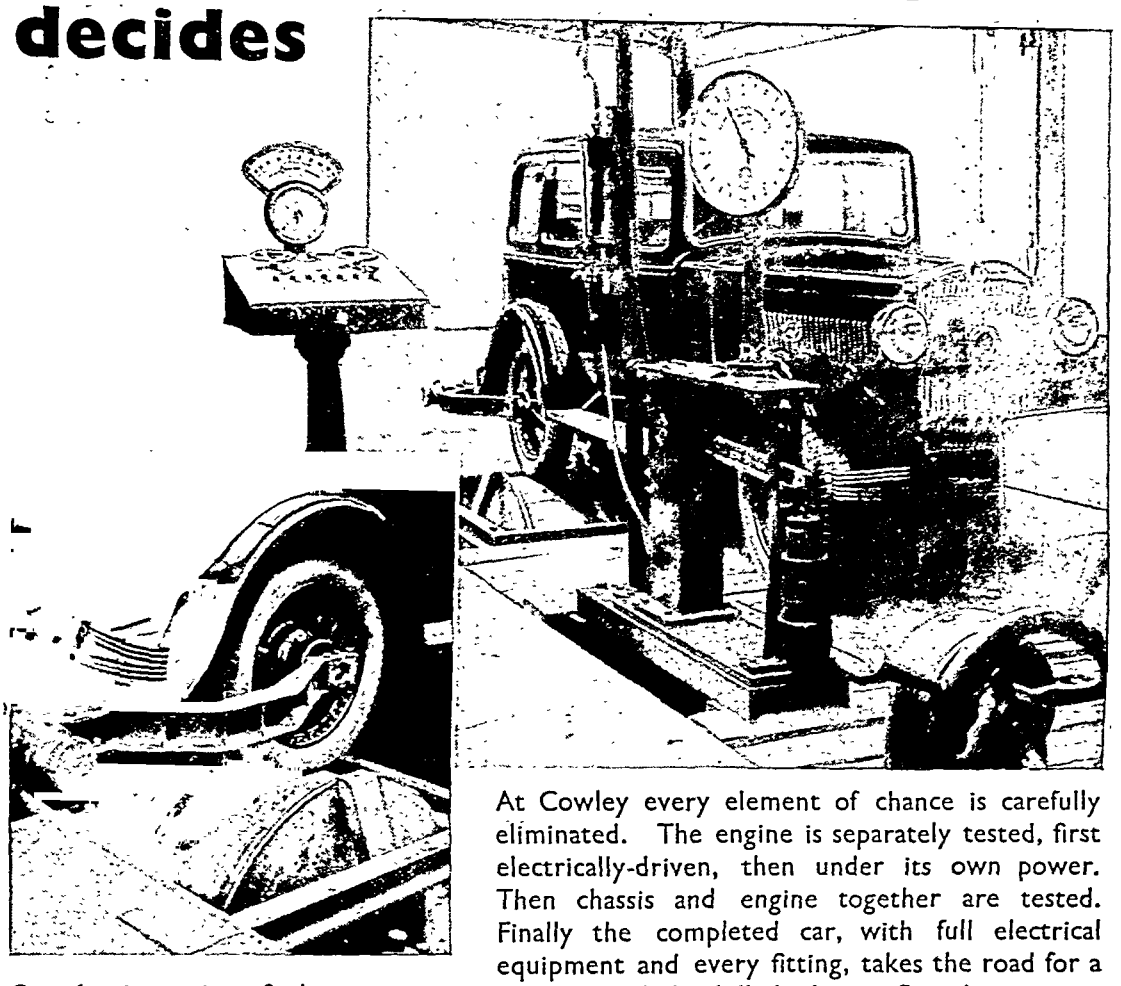
This concerns your home, and may not interest you as much as it will your wife.

The doctor's wife has more trouble in running her home efficiently and conveniently than most married women. Your irregular hours make catering difficult. Of course, you know more about the importance of proper diet then she does, or than we do; but probably, like most doctors, you don't often follow to the letter the advice you give your patients—about food. A hurried sandwich . . . a quick plate of cold meat, and you're off on a consultation.

That's where a Frigidaire would come in so useful. Instead of the makeshift sandwich there would always be some tempting cold entree or savoury kept fresh and delicious in Frigidaire's crisp, healthy cold. When you came in dead beat after a tiring day, there would be ice cubes for a long, long cold drink. Your children could have all the ice cream they wanted—it's easy to make in the Frigidaire ice trays. Their milk would have a low bacteria count. Salads would always be crisp and garden fresh; fruit would be cold and juicy.

Frigidaire without any attention keeps a steady temperature, low enough to arrest bacterial development. The running costs are negligible—a few pence a week.

The new Frigidaire plan for purchasing calls for an outlay of only £5 down. Isn't it worth considering. A postcard to our Bond Street showrooms will bring full information about a suitable cabinet.



FRIGIDAIRE

AUTOMATIC REFRIGERATOR

FRIGIDAIRE LTD. (Inc. in Canada), 141 New Bond St., London, W.1. Showrooms in all principal towns.

After every human test.. this infallible machine decides

Cams of varying severity are fixed on to these rollers. With each revolution of the roller, the cam strikes the wheel a terrific blow—worse than any road could inflict and this harsh treatment is continued for hours on end as an endurance test.

At Cowley every element of chance is carefully eliminated. The engine is separately tested, first electrically-driven, then under its own power. Then chassis and engine together are tested. Finally the completed car, with full electrical equipment and every fitting, takes the road for a stiff trial run which includes hill-climbing. But there is one test more merciless than all these. It is known as The Road Wheel Horse-Power Testing Machine and Road-Shock Tester. Place the car on its rollers and every stress and strain of actual running is mechanically recorded. You can switch on a 60 m.p.h. gale; you can alter the punishment inflicted by the rollers from that of an average arterial road to the very worst going the Colonies can show. All the unerring information gained goes to the steady improving of Morris cars; ensures the elimination of every conceivable risk; gives you trouble-free motoring.

THE MORRIS 1933 RANGE comprises 31 models from 8-25 h.p. priced from £100 —£395 ex works.

ARTHRITIS

In view of the B.M.A. Committee's specific recommendation of **Wheat germ*** as a source of the Vitamin B supply in the treatment of **Arthritis** and Allied Conditions, it is appropriate to quote the personal experience of a physician whose letter reads as follows:—

"From my own personal experience I know that the effect of BEMAX on cases of early Rheumatoid Arthritis is little short of marvellous. After three months all pain and swelling of the joints has disappeared, and there is a general feeling of well-being and vitality which I can only ascribe to the fact that BEMAX supplies the Vitamin evidently lacking in the ordinary diet."

————, M.B., Ch.B.

The proprietors of Bemax have received much other testimony to the same effect.

* *Prepared from the finest selected germ*, Bemax is particularly indicated in the treatment of Arthritic and Fibrositic disorders.

Its Vitamin B activity is about 360 International Units per ounce—nearly twice the daily requirement of a healthy adult.

For sustained administration the most reliable, convenient, and economical source of Vitamin B is Bemax.

BEMAX

THE RICHEST NATURAL VITAMIN TONIC FOOD

2/6d. size lasts an adult a month

Laboratory reports on BEMAX and a clinical sample for personal trial will be sent to any medical man on receipt of his professional card.

THE BEMAX LABORATORIES, UPPER MALL, LONDON, W.6

The Rose Corset-Belt

Efficiency with Elegance

THE ROSE CORSET-BELT is graphically shown (in these photographs) applied in an actual case of visceroptosis. It is important to observe that the *maximum amount of support* is given combined with a *definite improvement in the lines of the figure.* Similar Belts are made for cases of movable kidney, hernia, and post-operative support, *each garment being cut and fitted to individual needs.* We also specialize in a new style *Colostomy Corset* adapted to meet the requirements of the most fastidious. Madame Rose gives her personal attention to the correct interpretation of the doctor's instructions.

Your patients too will receive every satisfaction.

TO A PÆDIATRICIAN

to whom acidosis is a daily problem in young lives

THE child who will not eat, the child who eats too much, the child who is constipated, the child who suffers from diarrhœa—ACIDOSIS complicates each condition. It may be a skin eruption, an otherwise unaccountable listlessness and fatigue, sleeplessness, nervousness; a train of symptoms and no help from the patient.

You are in search of the best and safest measure to restore the alkali balance—and we have no hesitation in recommending Alka-Zane to you. If the satisfactory experience of others means anything, you will try Alka-Zane on this score alone. Nothing enters into the composition of Alka-Zane that is marked by doubt of its therapeutic value. Only the carbonates, phosphates and citrates of sodium, potassium, calcium and magnesium to form a palatable drink in solution. No lactates, no tartrates, no sulphates; no sodium chloride.

Alka-Zane may be dissolved in water and added to milk after effervescence has subsided.

Let us send you a trial supply. There is no obligation or cost.

ALKA-ZANE *for Acidosis*

The Treatment of Macrocytic Anæmias with MARMITE

Reports of clinical trials published recently (The Lancet, June 17th, 1933, p. 1283) afford striking confirmatory evidence of the hæmopoietic properties of Marmite.

Reference is made by the author of these reports to the successful results obtained by several other investigators who have used Marmite in various macrocytic anæmias—including the anæmia associated with cœliac disease and with sprue, as well as in true pernicious anæmia.

It is interesting to note that other yeast preparations and Vitamin B concentrates proved to be inactive curatively when tested on a number of cases of tropical macrocytic anæmia, but that these cases all responded to Marmite treatment. This observation on the superiority of Marmite as an anti-anæmic agent is in agreement with the findings of workers in other fields (Archives of Disease in Childhood, April, 1933) and tends to show that Marmite is of even more value as a medicament than was recognised hitherto.

MARMITE

(Registered Trade Mark)

In Jars: 1 oz. 6d., 2 oz. 10d., 4 oz. 1/6, 8 oz. 2/6, 16 oz. 4/6

Special quotations for supplies in bulk to hospitals and institutions.

"CYSTAZOL"

A Powerful Urinary Antiseptic

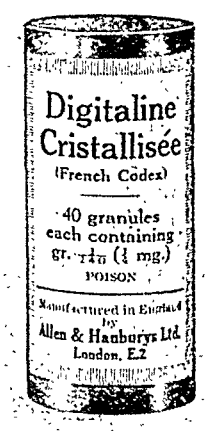
"Cystazol" is a combination of Hexamine with Sodium Benzoate: its action depends on the liberation of formaldehyde from the decomposition of the hexamine that takes place in the urine which has been rendered acid by the sodium benzoate moiety. "Cystazol" is employed with advantage in cystitis, bacilluria of all types, pellagra, gonorrhœa and septic conditions of the urinary tract generally.

COMPRESSED TABLETS of "Cystazol"

Supplied in bottles of 20, 40, 80, 160 and 500 (10 grain) tablets.

EFFERVESCENT GRANULES of "Cystazol"

Supplied in 8 oz. bottles containing 4 oz. by weight of Effervescent Granules of "Cystazol."



Descriptive literature and clinical trial sample will be sent post free on application.

Digitalin Granules "A. & H."

gr. $\frac{1}{240}$ ($\frac{1}{4}$ mg.)

gr. $\frac{1}{600}$ ($\frac{1}{10}$ mg.)

Physiologically Standardized

Digitalin Granules, "A. & H.," a British preparation, consist of the *Digitaline cristallisée* of the French Pharmacopœia. This substance is the most active principle of digitalis leaves, and, because of its reputation for uniform activity, it has long been popular, particularly on the Continent. Its use is recommended by high authority in cases where galenical preparations of digitalis have failed.

For Prescribing:
In tubes, containing 40 granules, 2/6 each
For Dispensing:
In bottles, containing 250 granules, 12/6 each
Subject to the usual professional discount.

Descriptive literature and clinical trial sample will be sent post free on application.

BISMULAIT
(DUNCAN)

A uniform and palatable preparation of Bismuth, containing 5 grains of freshly precipitated Oxycarbonate of Bismuth in each fluid drachm. It is readily diffusible and the Bismuth is presented in the minutest hydroamorphous condition. Bismulait is of the utmost value as a sedative or antacid in gastro-intestinal troubles.

Also the following Combinations:

BISMULAIT c PEPSIN

Contains 2 grains of Pepsin in each fluid drachm. An ideal preparation for the treatment of Dyspepsia.

BISMULAIT c SALOL

Contains 5 grains of Salol in each fluid drachm. For the treatment of Dyspepsia associated with fermentation.

Packed in 4-oz., 8-oz., and 16-oz. bottles.
Sample on application.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

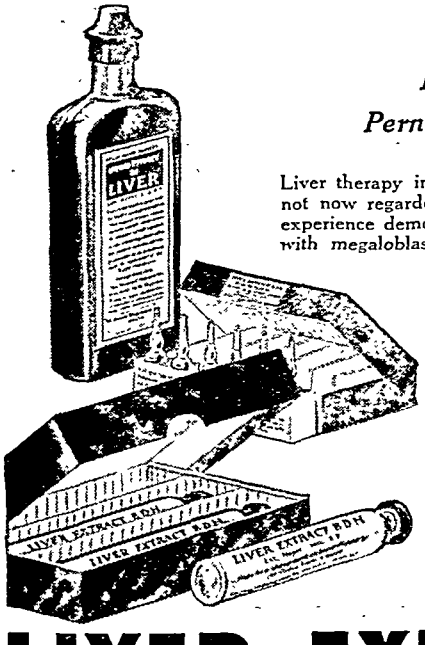
OESTROFORM

Oestroform is the pure crystalline ovarian follicular hormone. It is available for clinical use in sterile solution for injection, and in tablets for oral administration; both forms are accurately standardised and are of exceptionally high unitage, the solution possessing an activity of 1,000 units per c.c. and the tablets an activity of 1,000 units per tablet.

The value of Oestroform in the various conditions associated with metabolic disturbances of ovarian origin has been demonstrated recently by exhaustive clinical tests.



For example, in the treatment of vomiting of pregnancy, some very promising results have been obtained with Oestroform, great relief having been experienced by the injection of a fairly large dose—10,000 units three times per week.

In menopausal disorders also, Oestroform administration is proving to be of considerable value.

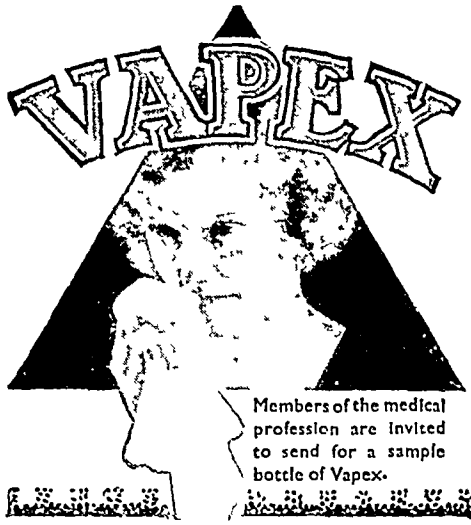
In the treatment of Anaemia

Pernicious and various forms of Secondary

Liver therapy in pernicious anaemia is an accepted routine, but its usefulness is not now regarded as being confined to anaemia of the pernicious type, clinical experience demonstrating that other forms of anaemia, particularly those associated with megaloblastic hyperplasia of the bone marrow, yield satisfactorily to this form of treatment; of these the anaemias of pregnancy and sprue are examples.

Furthermore, as a well-known physician reported recently (*Lancet*, March 18, 1933, p. 583), he has encountered frequently "*. . . borderline cases which did not exhibit the complete picture of that disease, though they improved more under liver treatment than other cases of anaemia. . . .*"



Liver Extract B.D.H. is a potent and standardised extract containing the whole of the haematopoietic principles of liver. It is supplied in the form of powder (Ext. Hepat. Sicc. B.P.) and in liquid form (Ext. Hepat. Liq. B.P.) for oral administration, also in sterile isotonic solution in ampoules for use by injection.

HUNDREDS OF MALTS WERE TESTED

to find the best *malt for* **BOURN-VITA**

The finest liquid malt is used in the preparation of Bourn-vita. It is prepared from barley of guaranteed British origin. For the production of a churn of liquid malt extract it is necessary to plant 1,095 sq. yds. of land with barley. Has it ever occurred to you how much care is expended in producing the Malt Extract?

(1) SELECTION. Only the finest barley, noted for its good malting properties, is selected.

(2) GERMINATION. After soaking, it is allowed to germinate under special conditions so that the vital changes associated with growth can take place in the grain.

(3) KILNING. The now "green" malt is subjected to a heating process to further those subtle changes so necessary for the preparation of the perfect malt extract.

(4) BLENDING. Work for the expert, so that the choice full flavour is assured in the finished extract.

(5) MASHING OR EXTRACTING. This process enables the diastase of the malt to act under ideal conditions, so that a dilute malt extract is produced.

(6) CONCENTRATING. The malty liquid is highly concentrated by a vacuum process which does not impair the exceptional properties of the original malt.

This process results in a malt of high diastatic power and exceptional purity. Malt is a great aid to digestion and assists in the rapid conversion of food into energy.

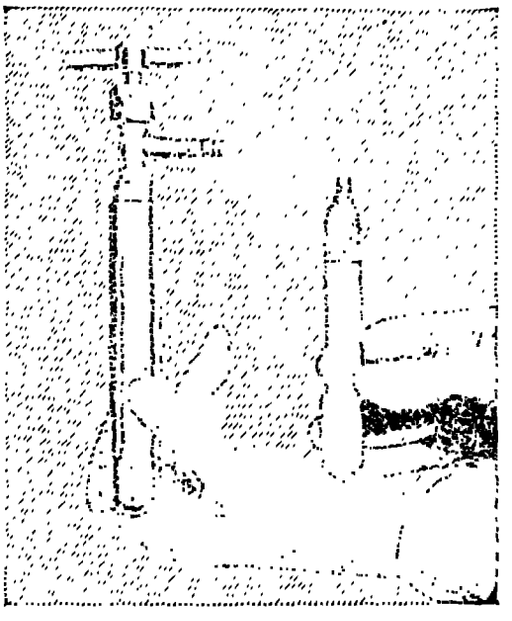
Experience teaches

that the physiological developments of the growing child call for the use of a graduated series of foods during the first twelve months of life.

This is the basis of the "Allenburys" Progressive System of Infant Feeding.

Experience proves



that the use of Dextrin Maltose during the process of manufacture as a protective colloid is the best means of "humanising" the casein of cow's milk.

This is the basis of the method of manufacture of the "Allenburys" Milk Foods.

This announcement regarding the "Allenburys" Foods is No. 10 of a series which will be continued.

CARBON DIOXIDE in General Practice

AN EASILY PORTABLE APPARATUS

CARBON DIOXIDE (CO_2), and OXYGEN & CARBON DIOXIDE MIXTURE, are now becoming more and more generally used, not only in all forms of respiratory emergencies, but in the routine treatment of chronic respiratory diseases such as ASTHMA, HAY FEVER, PNEUMONIA, WHOOPING COUGH, etc., etc.

In the past, these gases have only been available in cumbersome cylinders, so that the CARBON DIOXIDE, or GAS MIXTURE treatment, has often been difficult and expensive.

NOW, however, a simple compact apparatus is available in the Sparklet "POCKET RESUSCITATOR" (here illustrated). Measuring only 10 inches long, it can be carried in the handbag; a turn of a key **instantly** releasing the requisite stream of pure CARBON DIOXIDE, OXYGEN, or MIXTURE GAS when and where needed.

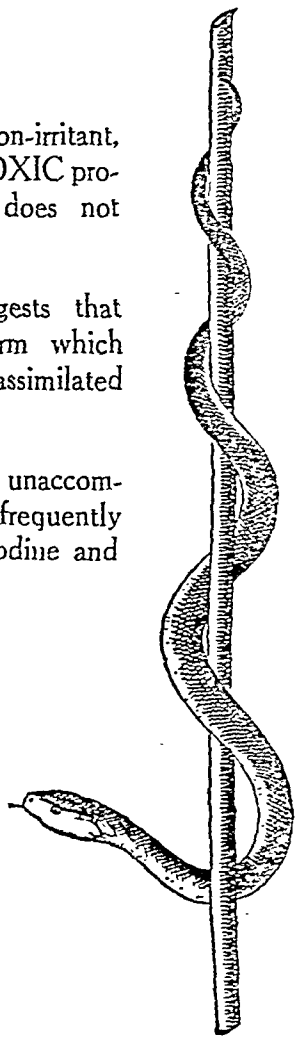
THERAPEUTIC NOTES

from

Oppenheimer Son & Co. Ltd.



Iodine Therapy

"ALPHIDINE"

ALPHIDINE is a non-irritant, relatively NON-TOXIC product of Iodine which does not cause Iodism.

Clinical experience suggests that the Iodine is in a form which is readily taken up and assimilated by the Thyroid Gland.

Its administration is unaccompanied by depression so frequently caused by the ordinary Iodine and the Iodides.

INDICATIONS:—All those conditions arising from a subnormal Thyroid.

HYPERTENSION, ARTHRITIS,

RHEUMATIC CONDITIONS generally.

Also valuable in fatty infiltration.

THOTH, EGYPTIAN GOD OF MEDICAL MAGIC, DEPICTED IN THE FORM OF HIS EMBLEM AND REPRESENTATIVE, THE CYNOCEPHALUS APE.—Temples and shrines to Thoth, "great in magic," existed everywhere in ancient Egypt, but the earliest was at Khemennu (later Hermopolis), and this became the greatest healing temple in the Nile Valley. Sick persons passing the night in the temple sought cure by divine revelation of the remedy received through dreams or oracle in response to prayer. The dog-headed ape was greatly revered in ancient Egypt from earliest times; he is the sacred animal and companion of Thoth, who was believed to be incarnate in him. In scenes of the "weighing of the heart," he sits on the pillar of the balance and reports the result to Thoth who records it.

DATE: From earliest times. The illustration c. 1580 B.C. COPYRIGHT

You can recommend Odol because it is safe.....

Odol Tooth Paste has earned the approval of Dental and Medical Practitioners not merely because it is an effective, antiseptic dentifrice, but also because it is *safe* — even for young children's teeth.

In the desire to remove quickly all surface dirt, stains or tartar there is sometimes a tendency to resort to abrasive pastes or powders which eventually have a highly detrimental effect upon the enamel and only a smooth, *triple-milled* tooth paste, such as Odol is, can be safely recommended.

Odol is in my opinion the finest dentifrice I have ever used, and I have sampled many. I have often recommended it to my patients . . . . and have found it very efficacious.
(Signed) M.C., M.R.C.S. (Eng.) L.R.C.P., London.

Your Tooth Paste is most refreshing and is really efficient, your Mouth-wash also. I have no hesitation in recommending both.
(Signed) The Principal of a Dental Hospital.

I find from personal experience that it is the only Tooth Paste on the market that really cleans teeth.
(Signed) A London Dentist.

After a thorough personal test I have no hesitation in saying that in my opinion it is by far the best preparation of its kind and I will certainly recommend it to all my patients.
(Signed) L.D.S., R.C.S.

A generous supply of trial samples sent on receipt of Professional Card.

A Paper
ON
OBSTETRICAL ERRORS*

BY

E. FARQUHAR MURRAY, M.D., F.R.C.S., F.C.O.G.
HONORARY GYNAECOLOGIST, ROYAL VICTORIA INFIRMARY; OBSTETRICIAN, PRINCESS MARY MATERNITY HOSPITAL, NEWCASTLE-ON-TYNE

It is important that the art of obstetrics should be as highly organized as possible. If engaged for a case we must assume full responsibility and not relegate to a nurse or midwife those matters which are essentially medical and obstetrical. Again, if we are usually called in by a certain midwife and find a condition which could have been recognized, and possibly prevented, at an earlier stage, then it is our duty to educate that midwife to the value of closer co-operation. One of the biggest errors made, and still being made, by the profession is that of allowing obstetrics to drift into the hands of midwives, clinics, and whole-time officers. Some of this may be inevitable and even desirable, but doctors are losing the supervisory and consultative interest in this work to the detriment of their practices. The backbone of a successful practice is midwifery, followed by child welfare.

Ante-natal Care

The supervision, manipulations, and decisions concerned with ante-natal care form one of the most fascinating studies in medical art. The absence of this care is a big error. The multitude of normal labours which occur without such supervision tend to belittle its value and to make people somewhat sceptical. Sooner or later a most devastating tragedy will shock the most casual in this regard. Such comparatively simple and not infrequent matters as the recognition of an occipito-posterior, a breech in a primipara, or a contracted pelvis which invites obstruction may, when properly dealt with, make all the difference between a triumphant success and maternal and foetal exhaustion, bruising, and even death. Ante-natal care is not merely safeguarding the lives of the mother and her child, but also making certain that they will emerge from their joint experience—the confinement—as undamaged from wear and tear as possible. What we have to aim at is that every baby is presenting head first as a polar lie and with its back anterior, and that the relation of the head to the pelvic cavity shows no unfavourable disproportion.

Occipito-posteriors are best dealt with by applying a pad over the child's back, and it is fixed in position with a tight binder. The bladder and bowels are kept empty, and the patient remains in bed for twenty-four hours. If the procedure fails, repeat it at the next week-end; and if it still fails, then apply it at the onset of labour.

In breech cases the error is often in diagnosis: the buttocks are mistaken for the shoulders. Palpate for the head at the fundus, and dip the fingers into the pelvis behind the pubic bones to feel for a deeply engaged head. Finally, make a vaginal examination. By one or other of these means it should be possible to arrive at a diagnosis. In cases of breech with extended legs, the lower pole of the foetus feels very like the foetal head. If faced with a breech presentation in a primipara ask yourself "Why is it presenting as a breech?" and exclude the presence of a contracted pelvis. If the pelvis is badly contracted leave alone and arrange for a Caesarean section, but if normal or doubtful then do a version and test the head to the brim. In carrying out a version always lubricate the abdomen with soap or oil; this makes the version easier. If failure results then try under anaesthesia. If there is still failure, then by means of external measurements and a careful estimation of the pelvic capacity per vaginam decide whether or not there is sufficient room for the breech to come through, always allowing for manipulations for possibly extended arms or legs. Failure of judgement in this respect will end in a very difficult extraction with a stillborn child, or, in gross cases, in retention of the head above the brim. Lubrication of the hands, gloved or otherwise, with ethereal soap makes the corrective manipulations during delivery much easier.

Contracted pelves are usually contracted at the brim or throughout. Some are only contracted at or towards the outlet, and they are the more treacherous, as the head engages well and gives an appearance of normality, while late in labour the moulding and caput may suggest proximity and invite a delivery with forceps. Pelvic measurements, therefore, should always be taken of the outlet as well as of the brim. With the more common types of contracted pelvis the head is high and even overriding the brim. This in a primipara is always suspicious, as the head is usually deeply engaged for some weeks before term. Measure the pelvis and test the head to the brim, if necessary under anaesthesia. With a reasonable degree of care it is possible to divide cases into those that *will*, those that *won't*, and those that *may* come through. The first are normal, the second are for Caesarean section, and the third group should be as small as possible. Such a thing as a trial labour should not be allowed to occur outside a home or hospital, unless expert assistance is available. There is a place for induction of premature labour, but only in cases with minor degrees of contraction, occasionally in primiparae, and rarely in atypical forms of deformity.

* Read at a meeting of the Border Division, March 23rd, 1933.

Absence of ante-natal care may allow the toxaemia of pregnancy to produce the kidney of pregnancy and its major crisis, eclampsia. Regularity of the bowels, routine urine testing every fourteen days till the last weeks, when it is done weekly, and, most important of all, encouraging the patient to report any unusual symptom will modify this danger. Oedema is not, as commonly believed by the laity, due to pressure, but is really a manifestation of renal deficiency. Don't hesitate to starve an albuminuric patient. Fluids are essential, and food may be withheld for a week or more with impunity. Fruit juice and stewed fruit and sugar may be given after a period and before proteins are added to the diet. In actual practice the routine testing of urine specimens would be best dealt with by the nurse if it can be so arranged.

The utmost need for ante-natal care is in the case of primiparae, as their first pregnancy and labour is a trial of their pelvic girdles and their metabolism. Multiparae must be watched carefully also. Their kidneys may be damaged, their lax uteri may allow malpresentations. Four such, with previously normal histories, arrived at a hospital with ruptured uteri. They had malpresentations which had been corrected by version. Three of them died. The *malpresentations or the versions should* have been dealt with earlier.

LABOUR

The dramatic obstetrics which impressed us as students, the difficult versions, embryotomies, decapitations, and so on, were largely owing to the absence of organized ante-natal care. The contrast between a timely Caesarean section in a case of badly contracted pelvis and a similar case dealt with late in labour *per vias naturales* requires no comment.

A great error during labour is to withhold chloroform. The patient's cries are unnerving the household, the atmosphere is tense, the doctor may be urged to terminate labour. Delivery may be the worse possible treatment in such a case. The patient, a primipara, may be only half-way through the first stage of a perfectly normal labour. Put her and the family to sleep by administering chloroform to the patient. Do not forget to do this when called in by a midwife to a case which you have never seen before. Quieten the household, get the history, and make a careful abdominal examination ; then wash up and make a careful internal examination, and arrive at *your final decision after sizing up the general* condition of the mother and the child. Morphine may be given, and also bromides and chloral ; but morphine should not be given if delivery is likely to take place within four hours of the injection.

Failed forceps, when analysed, are divisible into those due to errors of omission and those due to errors of commission. The former are neglect of ante-natal care, and the latter are forceful attempts to anticipate natural processes or incorrect attempts to remedy the neglect of ante-natal care. Cases admitted to hospital with the os uteri one-third or one-half dilated are merely given time to complete the natural process. The injection of pituitary extract is open to criticism. Having known of it being given to primiparae, and even primiparae with badly contracted pelves, I believe that the following is fairly sound advice: never give pituitary extract until you are fully conversant with obstetrics, and never to a primipara. Reserve its use for multiparae with a fully dilated os, and a head well engaged or low down, when it is merely a question of pushing or gently pulling the head over the perineum. Always dilute the extract and inject it gradually under anaesthesia. Another common cause of failed forceps is failure to recognize that the baby's head in an occipito-posterior case is not yet in the antero-posterior of the outlet. It is not always easy to detect, especially if there is much of a caput. It is still more difficult if the patient is lying in the left lateral position. Great help is obtained by delivering these patients in the cross-bed position, using either Clover's crutch or the obstetric straps to obtain the lithotomy position. The exact relation of the head to the outlet is then easily detected by inserting the left hand in the vagina in order to palpate it thoroughly, or even to feel for the ears. Once the condition is recognized, rotate into the correct position and apply forceps, but if impossible to correct manually then correct with the forceps and reapply them, after correction, before extracting the head. Another error is to attempt extension of the head with the forceps before the occipital protuberance on the child's head has descended below the symphysis pubis: feel for it. In the third group of failed forceps are degrees of pelvic contraction. Gross cases are obvious by abdominal examination alone. Moderate cases require a careful examination under anaesthesia of the pelvic girdle and foetal head. Ask yourself what has already been done and what remains to be done. The only possible alternative at this stage, provided the child is alive, may be a Caesarean section or, occasionally, a version. Do not be misled by the small size of the os in bad cases of contracted pelvis into imagining that the patient is still in the first stage. The os may never dilate any further owing to non-descent of the head.

It is a mistake to allow tears to occur, to fail to repair those that do occur, and to admit that they have occurred. The vexed question of tears is so bound up in the public mind with neglect that it is useful to be frank with ourselves and admit that they do arise in a very large number of primiparae. Much can be prevented, much is inevitable. The really important point is to realize when a tear is likely to be inevitable, and to anticipate it by a timely episiotomy, which should be median in position. The indication for this is a tense ostium vaginae which has produced a secondary caput on the child's head, and where, with each pain, there is blanching of the vestibule. This may, if neglected, lead to two sequels: a bursting tear of the perineum, vagina, and labia, and such laceration of the sphincter urethrae as to result in laxity and incontinence of urine later. Failure to repair tears adds to the risk of puerperal sepsis, and possibly, later, of prolapse developing. As a gynaecologist as well as an obstetrician, and knowing how uniformly well properly repaired lacerations heal, I cannot but believe that, whether the blame rests with the profession or, more likely, with the midwives, there is simply no attempt to repair much vaginal trauma. One error might be excused—namely, failure to recognize that an intact perineal surface is associated with concealed lacerations. Always examine for them. Repair cannot, with rare exceptions, be accomplished by means of silkworm-gut sutures ; they produce an external appearance of approximation, but they rarely manage to produce actual anatomical apposition. In order to effect this catgut should be used, either buried or superficial. Repair the vaginal tube, repair the rectal tube and sphincter when necessary, bring the levators together between them, and finally repair the skin edges. Tell your nurses not to count the stitches or to admit tears. Tell them to admit bruising ; the patient and her husband will thoroughly understand, and their minds be peaceful. This is not duplicity, it is common sense. A " tear " sounds horrible, a " bruise " sounds reasonable. When the baby has arrived examine at once for tears. If trivial, repair at once with catgut ; but if severe, then wait until the placenta has arrived and do a proper and deliberate repair in the cross-bed position.

Another error is mismanagement of the third stage. The main danger is at night when time hangs heavy and one wants to " get it over." We are all human ; but

unless an anaesthetic has been administered, then it is useful to note the time of delivery and to allow at least fifteen to twenty minutes to elapse before worrying about the placenta. Leave the uterus alone, or at most feel it from time to time. It will not let you down. If an anaesthetic has been given, then the uterus *may* let you down, so it is best to massage it gently and note when the placenta has left. Should it be necessary to go in for the placenta, then always give an intrauterine douche afterwards. Failure to do this is asking for sepsis. Never allow a binder to be applied until at least one hour after delivery, and palpate the uterus from time to time.

PUERPERIUM

The first three days are probably the most important. Get the bowels open early. An enema is an adjuvant, not an essential. Opening medicine should be given in twenty-four hours' time or earlier. Always be on the look out for sepsis. Influenza; pneumonia, debility, yellow atrophy of the liver, and breasts are often provided as an explanation for a sequence of events which are in reality due to septic processes. The headaches, shivers, malaise, and temperatures of a septic process are often attributed to influenza if it is prevalent. Chest conditions of septic origin are often manifest within three days of delivery, and to the inexpert might be believed to be of accidental origin. Rapidity of pulse, with practically no other symptom than increasing weakness, can be due to hyperacute sepsis, but may be attributed to shock or haemorrhage. Jaundice, with only moderate pyrexia, or even in the absence of pyrexia, can be due to a hyperacute haemolytic streptococcal infection and not to hepatic derangement. Septic temperatures and engorgement of the breasts are common on the third day. Always be on your guard about sepsis; always suspect it; and always look at the perineum and lochial discharges. Never give a vaginal douche without clear proof of vaginal sepsis. In the vast majority of cases it is merely perineal sepsis; therefore arrange for local swabbing with peroxide, 20 volumes, three times a day, followed by a jug douche of boric or weak lysol; and this is all that is needed. If there is vaginal infection apply similar treatment to the vagina. Very occasionally the uterus is to blame, but only rarely in the first instance. The difficulty of adequate nursing in outlying areas is obvious. The fact remains that such may be essential.

Three errors remain to be dealt with, although there are many others. Lysol, or any other such substance, is quite useful as an inhibitor of bacterial activity. It does not, except in its pure state, act as a reliable antiseptic. The only reliable antiseptic is a preparation of mercury, such as the perchloride (1 in 1,000) or the biniodide (1 in 1,000). Swabs, hands, and individuals passing from case to case can never be efficiently disinfected if they depend on lysol. With rare exceptions, never examine a patient when she comes to book you. She is nervous and self-conscious, especially if she is a primipara. Internal examinations are a rarity under modern conditions of ante-natal care. Do not tell a woman that she must never have another baby unless such an edict is based on the soundest medical, surgical, or obstetrical grounds. Such advice—in cases met with—has rarely been justified. The patient fears falling pregnant, and is panicked if she does. If such advice is given, whether justified or not, it is strangely out of place that no further advice follows. Finally, we must realize that the very essence and ethics of our existence are based upon the conservation of life itself. Therefore, safeguard the mothers with ante-natal care. Remember, when you are called in to see a case, the importance of time, sedatives, and careful decisions in labour, and always be on the look out for sepsis during the puerperium.

PANCREATIC LITHIASIS

BY

S. N. SENNETT, M.B., B.S.LOND., M.D.BERL.

CAPETOWN

Pancreatic lithiasis is a rare condition; the symptomatology is bewildering and the diagnosis beset with many difficulties. A review of the history and symptomatology may therefore prove interesting inasmuch as it may enable a diagnosis to be made more frequently in the living. Although pancreatic lithiasis was first observed by Regnerus de Graaf in 1664, its great rarity is such that nearly two and a half centuries later (in 1903) Lazarus was able to collect only eighty such cases described in the literature. In most of the cases the calculi were found at necropsy; in some the diagnosis was made of chronic pancreatitis of probable calculous origin, and in several instances the diagnosis was only made at operation (Lindsay, Link, Seeger, Hartman, etc.). In recent years, however, with the aid of roentgenology, a few more cases have been described, so that the condition is not quite so rare as had been supposed. Out of 11,000 necropsies at Guy's Hospital there were three cases only, and Opie in 1910 found two among 1,500 necropsies at the Johns Hopkins Hospital, all in elderly men. Rindfleisch, in 2,000 necropsies at Königsberger Medical Clinic, found only three cases. In the Mayo Clinic, where at every laparotomy of the upper abdomen the pancreas is palpated, eight cases have been discovered in fifteen years. Pancreatic calculi occur more frequently in men than in women: this is also consistent with the observation that chronic pancreatic disease is much more frequent in males than in females. Among the fifty-seven cases collected by Lazarus, forty-seven were in men and ten in women, and of these, thirty-seven were between the ages of 30 and 50 years.

The number of calculi varies greatly: usually five to ten are present; in rare instances there is a solitary calculus, but as many as 300 have been found (Lancereaux). A characteristic of multiple pancreatic calculi is that they are usually not faceted (unlike gall-stones). They vary in size from mere sand to masses the size of a walnut, and may be smooth or rough, soft or hard, and white, brown, or yellow. They consist chiefly of calcium carbonate or calcium phosphate, or even occasionally of calcium oxalate, which is somewhat surprising, as the pancreatic juice does not contain these salts, and is strongly suggestive of an inflammatory aetiology. This fact is, however, of great importance, as it is the lime salts which make the stones opaque to *x* rays. Rarely they consist of organic substance, and occasionally of lime salts, together with organic protein debris. It is of interest to note that pancreatic calculi have also been repeatedly found in animals, particularly in cattle.

Calculi probably never form in a healthy pancreas. All the evidence points to primary inflammatory changes in the ducts and in the parenchyma of the gland, with occlusion of the ducts (stasis) or invasion by bacteria as a secondary factor. Giudiceandrea demonstrated the colon bacillus with numerous long bacilli in pancreatic calculi, while in a second case he found numerous cocci and bacilli in the centre of a stone. On the other hand, Lindsay could not discover any bacteria in his calculi.

SYMPTOMS

Pancreatic lithiasis may be unaccompanied by noteworthy local symptoms indicating disease of the organ. Lazarus gave an account of such a case, in which death occurred with diabetes and pulmonary tuberculosis. At necropsy the pancreas was found to be converted into a

fibrous sac, and, notwithstanding the fact that the duct contained numerous jagged concretions, there had been no pain. In another instance (Wolf and Tietze) a man, 45 years old, who had never had any colic—in fact, no real pain at all—complained of an insatiable hunger and the passage of bulky stools. On *x*-ray investigation he was shown to have pancreatic calculi. Nevertheless, the most important and frequent symptom is pain. It is usually epigastric, and may be dull and continued, or intermittent, occurring in colic-like attacks, similar to those of gall-stones. In the case I described, a man, aged 37, complained for some four months of pain in the epigastrium, which radiated to both sides of the abdomen. The pain was dull and practically continuous, and was worse soon after food: it gradually became more severe, so that he was afraid to eat. He had no attacks of colic. Attacks of colicky pain have been characteristic of many of the cases reported (Lacoutre and Charbonnel, Einhorn, Pitt). Sometimes it is agonizing in character, and may be associated with vomiting, hiccup, tachycardia, cold sweat, and collapse. Chills and fever may at times occur. Severe attacks of colic-like pain may accompany the passage of calculi. In a case of Leichtenstern's, symptoms of biliary colic without jaundice were followed by the passage in the faeces of three concretions, the largest the size of a pea and composed of calcium carbonate without traces of bile pigments or cholesterol. In some cases pain has been localized in the epigastrium and under the left costal margin in the nipple line and radiating to the left side of the spine or the left shoulder-blade, or there may be, as Seeger has stressed, a left lumbar radiation. It is interesting to note that many of the cases recorded within recent years have had no typical colic attacks, but more of a dull continuous pain in the epigastrium, made worse some ten minutes after food (Sennett, Link, Orth, etc.), or simply a feeling of pressure in the upper abdomen (Meyer). Although the attacks of pain associated with the passage of pancreatic calculi are often accompanied by vomiting, which may be quite severe, in some cases there were attacks of colicky pain but no vomiting. Lindsay's patient had abdominal pain about half an hour after food, beginning as an ache in the region between the gall-bladder and the umbilicus, culminating in paroxysms of severe pain, doubling him up, and radiating to the left. The paroxysms were accompanied by nausea, but he never vomited. In my case there had also been no vomiting.

The passage of a pancreatic calculus through the diverticulum of Vater may cause temporary jaundice. A patient of Leichtenstern's suffered for two years attacks of a severe abdominal pain and vomiting, and on one occasion jaundice; at operation no gall-stones were found, and necropsy revealed numerous pancreatic calculi. In my patient there was no jaundice until shortly before death. In several instances a diagnosis of pancreatic lithiasis has been made during life from the passage in the faeces of calculi composed of calcium carbonate or phosphate, and free from bile: Leichtenstern made his diagnosis in this way. In a case of Minnich's, soft, friable concretions, as large as a cherry pip and containing carbonate and phosphate of calcium, were found for twelve days after an attack of colic.

Glycosuria has been a symptom of pancreatic lithiasis in a large proportion of the recorded cases. Lancereaux reports twelve cases in his series of forty; Lazarus, thirty-six in his series of eighty. Pancreatic lithiasis may exist for years without diabetes, and in the case described by Caparelli glycosuria appeared six years after the first attack of colic. Since glycosuria is not the result of occlusion of the pancreatic ducts, but of consequent chronic interlobular inflammation, diabetes results only after the lesion has become far advanced and has injured the islets of Langerhans (Atkinson and Hirsch). In Lindsay's second case the destruction of the pancreas was advanced and the pancreatic juice did not digest protein and fat at all, and starch only slowly. The urine contained sugar and acetone bodies in small amount. In his first case there was no glycosuria, and the pancreatic fluid showed rapid starch and slow protein and fat digestion. In Link's case there was also no glycosuria, and at operation, when he removed the calculi, he could demonstrate that there was little damage to the gland substance, although some chronic interstitial pancreatitis, chiefly of the interlobular type, was present. My patient also had no glycosuria at the time he was examined.

Changes in the stools due to disturbance of the pancreatic function are occasionally noted, but are not common. Fatty stools (steatorrhoea) were present in ten of the cases collected by Lazarus. Azotorrhoea, shown by the presence of undigested muscle fibres in the faeces, is even less common than fatty stools, and in only one of the eight instances in which this accompanied well-authenticated pancreatic disease was the pancreatic lesion caused by calculi. In my case the stools examined were certainly not "pancreatic fat stools," and showed no steatorrhoea or azotorrhoea. The loss of weight in association with pancreatic lithiasis in the absence of diabetes or disturbances of digestion is probably referable, in part at least, to inflammatory changes or other complications of the disease.

DIAGNOSIS

Although Friedrich stated that it was impossible to diagnose pancreatic lithiasis, there are now several cases on record in which the diagnosis has been made during life. The reason that diagnosis causes such great difficulty is, as Moynihan points out, because the recorded cases are so few as to leave the symptomatology indefinite. As, however, cases of pancreatic calculi have been diagnosed, one has to reckon with the possibility of such diagnosis, even if it is rare. In 1906 Zesas collected in the literature seventy cases of pancreatic calculi, of which only seven had been diagnosed during life. Since then other cases have been reported, especially during the past few years, in which the diagnosis has been made by radiology.

In cases of colic, particularly in those which make one think of possible pancreatic affections, the stools should be carefully examined for concretions, especially for the sandy formations which readily pass through the sieve, as larger concretions are frequently absent. In fact the diagnosis has been repeatedly made from these stone formations (Minnich, Glaessner, Leichtenstern, and others). No conclusion can be drawn from the chemical examination of organic stones, but from the much more common inorganic calculi—notably those chiefly consisting of calcium carbonate—and from the absence of faceting the diagnosis becomes very probable, although it is still possible for such concretions to have formed in the bowel.

Within recent years several cases of pancreatic calculi have been diagnosed by means of radiography (Meyer, Lindsay, Jacquelin and Quénu, Morrison and Bogen, Zukschwerdt, Gross, Wolf and Tietze, Haudek, Friedrich and Hoesch, Orth, Ohnell, Sennett), and in some instances it has been possible to confirm the diagnosis at either operation or necropsy. To demonstrate the fact that pancreatic calculi show up on a skiagram, Assman *x*-rayed a cadaver in which a pancreatic tumour was found containing calculi in the ducts, and obtained quite definite shadows in the photograph. In a case of Pforringer's a diagnosis of renal calculus was made in a patient who had suffered for some time from severe, sudden, colicky pains, which were getting more frequent, were localized in the right side of the abdomen, and were associated with vomiting. There was no jaundice. On

x-ray examination an intense shadow the size of a cherry was seen in the right renal region, although lying somewhat nearer the vertebral column than usual. The patient was operated on, but died from a post-operative haemorrhage. Post mortem a roundish concretion, which coincided both in size and in shape with the shadow seen in the skiagram, was found in the pancreatic duct. In the case of Ackman and Ross's, shadows were noted at the level of the first and second lumbar vertebrae. These were thought to be calcified glands, but on post-mortem examination were identified as pancreatic calculi. In Lacoutre and Charbonnel's case and in one of Hartman's cases, after pancreatic calculi had been removed at operation, the post-operative *x*-ray examination revealed stones which had been overlooked. On the other hand, Glaessner has shown that in a case in which he had diagnosed pancreatic calculi because of the finding of concretions in the faeces and the suggestive typical clinical course of the case, the *x*-ray diagnosis was negative, in spite of the fact that the calculi consisted mainly of calcium carbonate. Also, in Hartig's case the *x*-ray findings were negative, but stones were found at operation. Moreover, the interpretation of shadows found in the upper abdomen is often difficult, so that before making a diagnosis of pancreatic calculi it is necessary to exclude the possibility of the shadows originating in the kidney, gall-bladder, or calcified lymph glands. If there is any suspicion of pancreatic calculi the *x*-ray examination and the searching for and the chemical examination of any concretions in the stool are of prime importance in diagnosis.

In addition, any possible disease of the pancreas should be carefully investigated. The clinical course of the case should be watched, especially as regards colicky pains, jaundice, composition and appearance of the stools, examination of the urine, salivation, etc. If the question of a renal calculus should arise it should be excluded by cystoscopy and ureteral catheterization. If cholelithiasis has been diagnosed and the patient operated upon the pancreas should be examined, particularly if gall-stones are not found, although even in the presence of gall-stones the pancreas should be carefully palpated if there is any suspicion of pancreatic disease.

TREATMENT

Statements concerning the treatment of pancreatic lithiasis are necessarily vague, since few cases have been recognized during life. Glaessner, however, claims to have cured his two patients by medical means—namely, a ten-days' course of olive oil followed by a course of Carlsbad salts, since when his patients have kept perfectly well. The efficacy of this form of treatment is, however, open to grave doubts. In most cases surgery seems the best hope, and cases of operative removal of the calculi have been not infrequently recorded in the literature (twenty-six in all, according to Seeger), and in most cases with excellent results. It must be noted that, even at operation, stones may be missed owing to the extensive fibrosis making palpation of the pancreas difficult. Rink and Sistrunk have called attention to a peculiar crepitus that often exists when there are multiple stones.

CONCLUSIONS

1. The symptoms of many of the cases described are diverse. Pancreatic lithiasis may be unaccompanied by noticeable local symptoms indicating disease of the organ, and, on the other hand, very definite symptoms may show that the pancreas is diseased.

2. In many of the cases recently diagnosed by radiology the absence of colic is a noteworthy feature. In the earlier cases, which were mostly diagnosed by the passage of inorganic calculi following attacks of colic resembling biliary colic, these attacks were stressed as a feature in its symptomatology.

3. Radiology, especially if carried out in conjunction with the other methods of investigation outlined above, offers the best means of diagnosing an undoubtedly very rare condition.

ACUTE PSOAS ABSCESS

BY

B. R. SWORN, M.B., F.R.C.S.

STAFFORD

The great majority of psoas abscesses are chronic in nature, and usually secondary to a tuberculous focus in the vertebral column or pelvic bones. A certain number, however, are more acute. The fact that the correct diagnosis is seldom made in these cases seems to be due mainly to the possible existence of the condition not being realized ; for the clinical signs are constant and characteristic. Although the older textbooks, such as Erichsen's *Surgery*, contain a fairly comprehensive list of the possible sites of origin of psoas abscesses other than the spine, and the signs which may be of help in their differential diagnosis, most of the modern textbooks give the impression that the condition is practically always associated with spinal disease. Some of them do not even mention any other cause, while others briefly refer to the possibility of the abscess being secondary to lesions such as suppurative appendicitis, perinephritis, or sacro-iliac disease. The references in the literature are scanty, but there are indications that this is due more to the condition being overlooked than to its rarity.

Baer, Bennett, and Nachlas[1] discuss forty-two non-tuberculous psoas abscesses seen at an orthopaedic department. Of these, twenty-four were seen in four years. They state that the cases were incorrectly diagnosed by good clinicians and sent to an orthopaedic surgeon, because it is generally believed that such abscesses must be due to disease of the spinal column or the skeletal portion of the pelvis. A summary of the possible primary lesions is given, and special attention is drawn to those abscesses following suppuration in the retroperitoneal lymph nodes, but there is no indication of the number which were thought to have arisen in this way. Behrman[2] describes four cases seen at a children's hospital during one year. Of these, two were operated on for acute appendicitis ; one was diagnosed as acute arthritis of the hip and the other as Pott's disease. He suggests that the abscesses might be secondary to lower pole perinephric suppuration, since the arrangement inferiorly of Gerota's fascia readily permits spread of an infective process downwards. He quotes Israel[3] and Wolkow and Delitzen[4] in support of this view, admitting, however, that the only positive evidence was the presence of a raised cellular count in the urine of three of his cases. One case of staphylococcal psoas abscess is reported by Rocher and Malaplate.[5] A thorough examination of this patient disclosed no primary infective focus, and although there is no mention of a blood culture having been done, these writers appear satisfied that the condition arose in the course of a staphylococcal septicaemia. They mention that before operation it was undecided whether the abscess was primary or due to spread from a perinephric focus, but no evidence of the latter was found during the exploration. Damm[6] also described a case of acute psoas abscess in which the origin could not be traced from the vertebral column or sacro-iliac joint. The author did not consider that it was of a tuberculous nature, but the actual bacteriological cause does not seem to have been established.

CASE RECORDS

The following three cases were seen by myself during the course of one year, and in each case the abscess appeared to be definitely pyaemic in type.

CASE I

F. Q., female, aged 1 year 3 months. Admitted to hospital on February 4th, 1932. The child was very ill. A superficial abscess was found over the upper part of the back. This was drained, and a haemolytic streptococcus was cultured from the pus. On February 12th the left hip was found to be in fixed flexion of about 75 degrees ; other movements were normal. A radiogram of the spine, pelvis, and hip showed no bony abnormality. A left psoas abscess was opened and drained through an inguinal incision on February 15th. Haemolytic streptococci were cultured from the pus. A few days later a superficial abscess developed over the left pectoral muscle, and a similar organism was recovered from the pus. The abscesses cleared up satisfactorily after drainage, but the child continued very ill with a typical septicaemic temperature, which only gradually subsided after about four weeks. The hip remained flexed, and a radiogram taken on March 17th showed a separation of the upper epiphysis of the left femur. There were no signs of an acute infection of the joint. The limb was put up in a plaster-of-Paris splint, and a satisfactory position was obtained. The patient then developed measles, but made a good recovery.

CASE II

S. C., female, aged 11 years. Admitted February 11th, 1932. Febrile attack five weeks before, followed by stiffness and pain in the right hip. State on admission: temperature 101.4°, pulse 108, pale and ill. Right hip held flexed nearly to a right angle ; other movements at the hip were normal. Blood count: 20,000 white blood cells, 80 per cent. polymorphs. Urine contained a trace of albumin ; there were no other abnormal constituents. A radiogram of the spine, pelvis, and hip-joint showed no bony change. On February 18th a right psoas abscess was drained through an inguinal incision. *S. aureus* was cultured from the pus. Discharged on March 3rd. General condition very good. Hip straight.

CASE III

B. B., male, aged 62 years. Admitted February 12th, 1933. No previous illness of importance. Indefinite onset of pain in the right groin two weeks before, which had become steadily worse. For the last few days the patient had been unable to straighten his right hip. A swelling had been noticed in the right groin for three to four days. State on admission: general condition fairly good ; temperature 99°, pulse 100. Fixed flexion of the right hip to about 40 degrees. Other movements of the hip were normal. A rather hard mass could be felt in the right iliac fossa running down almost to Poupart's ligament. No definite fluctuation was obtained, and the mass was at first thought to be enlarged glands. Nothing abnormal was found in the rectum or on examination of the spinal column. A radiogram of the spine, pelvis, and hip showed no bony abnormality. On February 18th fluctuation was obtained in the swelling in the right side, and a right psoas abscess was opened through an inguinal incision after aspiration with a needle. *B. pfeiffer* in pure culture was recovered from the pus. Discharged on March 4th with no symptoms. Flexion deformity of the hip quite cleared up.

Note by Dr. J. Menton

"The isolation of *B. influenzae* from the pus of this psoas abscess is interesting, especially in view of the fact that your patient does not give a history of recent influenza. I have encountered instances where the same organism appears to have caused meningitis, and in several of these cases the meningitis seemed to be the outstanding lesion, and no evidence of general infection was forthcoming. I am stressing these points in view of the present controversy on the role of this organism in the cause of disease."

DIAGNOSIS

The correct diagnosis of an acute or subacute psoas abscess should be fairly simple if the possibility of the condition is borne in mind. As a rule the patient has been ill for at least some days before the abscess appears, and complains of pain on the affected side running down into the groin or leg. This pain may be neuralgic in character and due to involvement of the lumbar nerves running in intimate relation to the muscle. The outstanding clinical sign is fixed flexion of the hip, and the degree of flexion is considerably greater than is likely to be found with simple spasm of the psoas from the irritation of a neighbouring inflammatory lesion, such as an acute appendicitis. Occasionally this sign may be present with an acute inflammation of the muscle without abscess formation, as in the case described by Nicolas, Lebeuf, and Charpy.[7] In addition to the amount of flexion found in these cases, the deformity will usually persist even under full general anaesthesia. The fixed flexion of the

hip, and pain on attempted extension, not infrequently leads to a diagnosis of acute arthritis, but thorough examination of the hip will show freedom of all other movements if the flexion of the joint is respected. Where the condition is not too acute for the patient to walk, a limp is always complained of, and there is considerable apparent deformity in the standing position. This, however, readily disappears when sitting, although a slight scoliosis may persist. There is no tenderness on percussion over the vertebrae, and no spasm of the erector spinae muscles, but occasionally deep tenderness may be elicited in the lumbar triangle.

Examination of the abdomen reveals some muscular rigidity on the corresponding side, and an underlying tumour may be felt. If the upper part of the psoas sheath is involved the thickening and tenderness found on bimanual palpation of the loin are strongly suggestive of a perinephric abscess. The acute abscess tracks outwards into the sheath of the iliacus, and, unlike the chronic one, seldom passes deep to Poupart's ligament into the thigh. A radiogram of the spine and pelvis will be negative, but it is said that there may be haziness of the sacro-iliac or hip-joints if the abscess overlies them, and this may be sufficient to cause a suspicion of early involvement of these joints.[1]

TREATMENT

Treatment consists, in the first instance, of aspiration of the abscess, and—if the pathological examination confirms the diagnosis by demonstrating pyogenic organisms in the pus—adequate drainage. The usual incision is one made parallel, and slightly internal to, the anterior third of the crest of the ilium, cutting through the muscles and opening the abscess behind the peritoneum. If the case is one of pyaemia, the best results are often obtained, as in other pyaemic abscesses, by withholding drainage until a definite abscess has formed. The subsidence of the local condition is usually satisfactory and rapid. A light extension may be applied to the thigh to overcome the flexion at the hip; this is especially indicated in children, in whom a pathological dislocation may readily occur, a complication which is extremely easily overlooked.

SUMMARY

The true origin of the acute psoas abscess may be difficult to decide, and although most of them are said to be secondary to a perinephric abscess or to suppuration in the iliac glands—diagnoses which are difficult to disprove—yet there can be little doubt that a certain number are pyaemic abscesses commencing within the muscle sheath. In favour of this supposition are: the antecedent illness so often present; the not infrequent occurrence of other pyaemic abscesses; the rapid subsidence of the local condition, so characteristic of the pyaemic abscess; and the lack of evidence of perinephric suppuration.

In one of the reported cases[5] the perinephric tissue was explored by the lumbar route, and it was not until the psoas sheath was opened that pus was found.

The three cases described in this paper are almost certainly pyaemic in origin, the abscesses being limited to the muscle sheath, no communication with surrounding structures being found.

I wish to express my gratitude to Mr. C. M. Page for permission to publish the first two cases, which were under his care at St. Thomas's Hospital, and to Dr. J. Menton for his advice and help.

RECURRENT VOLVULUS OF THE PELVIC COLON

BY

D. LIGAT, M.B., F.R.C.S.

SURGEON TO THE BUCHANAN HOSPITAL, HASTINGS; FORMER HUNTERIAN PROFESSOR TO THE ROYAL COLLEGE OF SURGEONS

AND

T. D. OVEREND, M.R.C.S., D.M.R.E.CAMB.

RADIOLOGIST TO THE BUCHANAN HOSPITAL, HASTINGS

(With Special Plate)

It is perhaps justifiable to state that recurrent volvulus of the pelvic colon has not yet attracted a great deal of attention. Although its existence as a clinical entity has long been recognized, it seems likely that a considerable number of cases escape notice. The clinical features are inconstant, confusing, and evanescent, and, in addition, are often overshadowed by those of some intercurrent lesion. Also, it is not perhaps too much to say that recurrent sigmoid volvulus does not immediately occur to the investigator as a probable cause of obscure abdominal symptoms. Such cases are not invariably subjected to radiological investigation, and even when this is carried out the methods adopted are not always those best suited for the display of colonic anomalies. In our experience, however, recurrent sigmoid volvulus is not an extraordinary rarity, and it is our belief that, apart from the danger of fatal strangulation, it is responsible for a considerable amount of avoidable disability. The diagnosis in such cases can be of great difficulty; the clinical picture can easily be confounded with that of abdominal neurosis, colitis, or some pelvic trouble in women; and the differentiation from such conditions can only be effected by a close study of the clinical history, supplemented by a radiological investigation along modern lines.

LITERATURE

The standard textbooks of surgical and radiological diagnosis give adequate descriptions of the signs to be observed when the acute abdominal emergency has arisen. They are, however, unsatisfactory guides to the recognition of the recurrent type of sigmoid volvulus. Reference to the works of such authorities as Miles and Paterson Brown, Schinz, Baensch and Fnedl, Albrecht, Kantor, Cawadias and Rankin, Bargen and Buie, shows that the special syndrome presented by this condition is either ignored completely or dismissed as a rarity of small practical importance. Edgren studied the previous clinical history in acute volvulus, obtaining prodromal signs in a large number; these might be either attacks of abdominal distension or simply obstinate constipation. The hereditary factors were emphasized by Greiffenhagen, and by Plaut, who attended both a father and a son with sigmoid volvulus. Lockhart-Mummery also described the two types of chronic volvulus, one with attacks of pain and distension, the other with attacks of obstinate constipation and discomfort. Radiograms illustrating potential volvulus were published by Jordan. The chronic obstruction due to incomplete volvulus has been described by Zachary Cope and by Braun. A helpful account of the syndrome of recurrent volvulus is given by Hamilton Bailey, who notes, besides the previous constipation and pain, the diarrhoea and passage of flatus following spontaneous reduction. Berg records a case of recurrent volvulus occurring in a megasigmoid in a young woman, with attacks of pain and distension in the left iliac fossa—the radiogram showed actual torsion of the mucous folds of the colon. Retzlaff has noted cases of this condition with attacks of pain and distension and obstinate constipation. The most important contribution to the study of sigmoid volvulus was made by Laurell, who described two cases, showing pain and watery blood-stained diarrhoea without local distension (von Wahl's syndrome). His article contains a full discussion of the pathology and symptomatology of sigmoid

volvulus, with an interesting account of the radiological signs. Adamson and Aird have shown, by section of the presacral nerves, that the condition of megasigmoid is due to over-action of the sympathetic system.

ANATOMY AND PATHOLOGY

The pelvic colon is that part of the great gut lying between the brim of the true pelvis and the third piece of the sacrum: it generally conforms to one of three types: (1) The first and commonest type is that in which the pelvic colon lies at first in contact with the left pelvic wall; it then runs across to the right side of the pelvis, and bends back towards the middle line, where it turns down to join the rectum at the third piece of the sacrum. (2) In the second type it is longer. It passes over to the right as before, and then crosses over to the left pelvic wall, thus making an S-curve before joining the rectum at the usual level. (3) In the third type it is abnormally short and may be devoid of mesentery.

The mesentery of the pelvic colon is a fan-shaped fold, attached to the posterior abdominal wall. Its arrangement gives the pelvic colon a narrow pedicle, which can be further narrowed by fibrotic contraction due to chronic inflammation. The pelvic colon has only one function, which is to act as a storehouse for faecal matter: it has practically no absorptive functions, and its secretory powers are probably limited to the production of mucus for lubrication.

Excessive length of the pelvic colon may be regarded under three heads:

(1) *Persistence of a Foetal Type.*—Congenital elongation of the pelvic colon, apparently due to arrested development, occurs as a sporadic variation and is hereditary. It may take the form of an inverted U, lying in the right side of the abdomen. As the limbs of this U are closely approximated, an axis of rotation is present from birth. Sir Arthur Keith has informed us that this type corresponds in many respects to the normal foetal condition. The enormous elongation of the sigmoid colon, in which this part of the bowel may exceed the rest of the colon in length and may wander into any part of the abdomen, has been described by Kienböck as the "sigma elongatum mobile," and by Lardennois and Aubourg as "dolichocoly."

(2) *The Megasigmoid.*—This condition, associated with gross dilatation of the lumen, may occur by itself or in conjunction with the general colonic changes of Hirschsprung's disease. It does not seem to be in itself a definitely predisposing factor for volvulus. It appears to be due to a neuro-muscular imbalance between the sympathetic and parasympathetic systems.

(3) *The Acquired Type.*—This is an elongation of the pelvic colon due to an adaptation to dietetic habits. The redundant pelvic colon found in Russia and the Baltic States has long been familiar to Russian and German surgeons, and is responsible for the extraordinary frequency of sigmoid volvulus as an acute abdominal emergency in eastern Europe—some Russian hospitals showing it as forming 30 per cent. of all cases of acute intestinal obstruction. It is not a racial characteristic, as it is common among Russian Jews as well as among Slavs, while it is rare among Jews elsewhere. It is attributed to the coarse vegetable diet, rich in indigestible cellulose, which would make greater demands on the pelvic colon as a faecal storehouse.

Volvulus of the pelvic colon consists in a torsion of the gut, either on its mesenteric axis or on its own long axis. These two forms of torsion may coexist. Torsion to the extent of a half-circle may occur without any interference with normal function. More complicated types of volvulus are sometimes encountered. The factors underlying the genesis of a volvulus are primary, secondary, and tertiary, or directly exciting. The primary factor is the abnormal length of the pelvic colon. The secondary factors are: (1) elongation of the pelvic mesocolon, (2) narrowing of the base of attachment of the pelvic mesocolon to the sacrum, and (3) the formation of an axis of rotation by adhesions or by close approximation of the entrance and exit loops of a coil of bowel.

For the actual crisis to arise the directly exciting cause is most often a physical strain, but violent peristalsis from the abuse of purgatives and other causes may also play a part. It appears reasonable to regard sigmoid volvulus as essentially a dormant condition, subject to sudden crises, which latter may assume either a major or a minor form. Clinical attention has been chiefly focused on the major type of crisis, in which the degree and duration of the torsion are sufficient to interfere seriously with the function and circulation of the bowel. Such a case is characterized by enormous abdominal distension and absolute obstruction, while pressure on the veins leads to congestion, and eventually gangrene, with resulting peritonitis. The minor type of volvular crisis is, in our opinion, very much more frequently encountered than the major type, though it is more difficult to diagnose, as the patient is nearly always seen during a latent period. No physical signs are present at this time, so that the clinician is dependent on the history, which may be extremely difficult to elucidate. Also, the clinical history may be variable in accordance with the special features of the case.

VARIETIES AND INCIDENCE OF VOLVULUS

The clinical types of recurrent sigmoid volvulus can hardly yet be defined, but certain features appear with sufficient frequency to suggest a provisional classification.

1. The first type of case shows severe and continuous constipation, perhaps with some discomfort or aching in the back or abdomen. Some are chronic and do not show anything in the way of a crisis, in others a minor crisis occurs periodically, in which the symptoms are accentuated. Constant or recurrent constipation may occur in any type of volvulus.

2. The second group of cases may either have some constipation during the latent period or may be free from symptoms during this time. These patients are subject to recurrent attacks of torsion, causing severe spasmodic pain and local distension of the bowel, but the torsion is not sufficient to occlude the veins.

3. In the third group, which is really only a severer form of the second, the torsion during a crisis is more marked and causes interference with the venous return. Such cases have recurrent attacks of severe pain with local distension and watery or blood-stained diarrhoea. The venous congestion induced by the twist causes a transudation into the bowel lumen, which is stored in the affected loop until it is set free by spontaneous reduction, when it appears as diarrhoea, watery or blood-stained according to the degree of torsion. The occurrence of the diarrhoea *after*, rather than during, the attack of pain is thus a point of diagnostic importance. The pain is very severe and may cause fainting. The cases showing von Wahl's syndrome of pain and diarrhoea without distension belong really to this group; the absence of distension is more apparent than real, as the affected loop may be incarcerated in the pelvis and so give little evidence as to its condition. The loss of fluid caused by the diarrhoea accounts for the extreme emaciation shown by patients in whom the attacks are severe and frequent.

The usual figures give a proportion of 4 males to 1 female as sufferers from the acute abdominal emergency,

or major crisis of sigmoid volvulus. It will be seen that in our own series there is a slight female preponderance. We do not attempt to draw any far-reaching conclusions from such a short series, but this finding is at least suggestive of the idea that the predisposing factors are fairly equally distributed between the two sexes, and that it may be the more energetic life led by the average adult male that renders him more liable to the major crisis.

RADIOLOGICAL INVESTIGATION

Fischer was the first to evolve a satisfactory technique for the examination of the air-and-barium-filled colon, which has been well described by Fleischner as the transformation of the colon into a translucent tube. From another angle the researches carried out on the digestive relief pattern by Forssell, Berg, Chaoul, Albrecht, and many others led finally to the work of Knothe, who has elaborated the methods of demonstration of the colonic relief. These methods have recently been ably summarized by O'Sullivan and Kadrnka.

Our own technique is based on those of the workers already mentioned, and generally comprises three stages:

1. The filling of the colon with a watery solution of barium containing tragacanth, and the study of the colonic contours.

2. The evacuation of the barium and the study of the colonic mucous membrane in sections, with the aid of graduated compression.

3. Fractional inflation of the colon with air to obtain a clear view of the anatomical relationships of the colon.

The radiological signs may be direct or indirect. Direct signs can naturally only be seen when the bowel is actually undergoing a crisis, or when the anatomical features keep it perpetually on the verge of one. Two direct signs have been observed by us: (1) actual screwlike torsion of the mucous folds of the colonic relief. (We have only observed this sign twice; it is seen in Case 2. As far as we are aware this sign has been previously described only by Berg. Manifestly it can only be due to torsion of the bowel on its long axis.) (2) The coils of bowel may be seen twining over one another as in Case 3. Indirect signs are afforded by a study of the anatomical features of the colon, which may result in the discovery of a loop of bowel with fixed and approximated limbs, or some other cause for a potential axis of rotation. It must be remembered that we are dealing with a dynamic and not a static condition, and that to arrive at a diagnosis an effort must be made to understand the potentialities as well as the actual anatomical facts. Naturally, the accidental discovery of a potential volvulus in a patient who has never had any symptoms attributable to it is of no significance, but when the clinical history is suggestive of volvular attacks, such a finding becomes of great importance.

A short account of some illustrative cases is given below.

CASE RECORDS

Case 1.—Jane D., aged 18. History: constipation in infancy, recurrent attacks of pain in left iliac fossa since age of 3, also attacks of severe constipation, fainting attacks at stool, and a visible swelling in left iliac fossa. The attacks of pain and distension are getting more severe, they are frequently brought on by physical strain, and the distension is described as a sausage-shaped swelling in the left iliac fossa, the appearance and disappearance of which was sudden. A barium enema (see radiogram, Fig. 1 on Special Plate) showed a redundant pelvic colon with a loop fixed at its two extremities, forming a suitable axis of rotation for a volvulus. A diagnosis of recurrent sigmoid volvulus was made. A preliminary caecostomy was performed, with a view to excision of the loop. This was badly borne, and the second operation was abandoned. The attacks of pain and distension continued, and six months later the excision of the redundant loop was carried out and end-to-end anastomosis performed. Since this the patient has been free from symptoms, and the most recent report states that she has gained over twenty pounds in weight, and is able for the first time in her life to lead an active open-air existence.

Case 2.—Katherine F., aged 26, a trained nurse. For about a year had suffered from periodical attacks of severe abdominal pain with distension. Attacks were brought on by physical strain, and on account of them she had had to give up the practice of her profession. Much loss of weight and some vomiting. Tenderness in both iliac fossae. Severe constipation. Barium enema (Fig. 2, Special Plate) showed a long sigmoid colon of the second type, with torsion of the mucous folds higher up. Recurrent sigmoid volvulus was diagnosed. The redundant sigmoid was excised and end-to-end anastomosis performed; the appendix was also removed. Her most recent report states that she has been free from symptoms since the operation (ten months), that she has been back at full work for several months, is feeling perfectly well, and has gained weight.

Case 3.—Charles P., aged 19, complained of aching pains about the umbilicus since he was 14. Recurrent attacks of pain set in about a year ago, and were always followed by copious watery diarrhoea. An inflamed appendix was removed nine months ago. Six months ago the attacks began to increase in frequency and severity, and were now accompanied by distension as well as by the diarrhoea. A particularly severe attack led to his admission to hospital. A barium enema (Fig. 3, Special Plate) shows an enormous loop of pelvic colon on the right side, and the actual twining over of the coils to form a volvulus. The diagnosis of recurrent volvulus occurring in a congenitally elongated pelvic colon was made. The redundant loop was excised and lateral anastomosis performed. There has been no return of symptoms during the five months following this operation.

Case 4.—Leonard E., aged 3½, was admitted with an eight-day history of severe constipation and intermittent pain in right and central abdomen. On examination he was seriously ill, with much abdominal distension. The symptoms subsided and the barium enema (Fig. 4, Special Plate) showed a large redundant loop of pelvic colon running up into the right abdomen. This was considered a potential volvulus of the same type as Case 3, and the opinion was formed that he had passed through a minor crisis of torsion. He presented other stigmata of degeneration, and his intelligence seemed subnormal. It was not considered advisable to intervene, but a very guarded prognosis was given. Since then he has again been admitted to hospital with a similar attack, which also subsided spontaneously.

These last two cases are instances of persistence of a foetal condition.

In addition to the foregoing, the following cases also came under our notice during the period from February, 1932, to April, 1933.

Case 5.—Female, 41 years. Always very constipated, for last two months attacks of pain, distension, and watery diarrhoea, also rectal haemorrhage. Very emaciated.

Case 6.—Male, 34 years. Occasional attacks of severe abdominal pain with distension, followed by watery diarrhoea; duration over last ten years.

Case 7.—Female, 46 years. Attacks of severe pain, during which she faints, followed by copious watery diarrhoea (two years). Much emaciation.

Case 8.—Female, 64 years. Severe constipation, continuous for last two years; also attacks of severe pain with great distension and copious watery diarrhoea, which has been blood-stained. Much emaciation.

Case 9.—Female, 12 years. Seen in attack of severe abdominal pain with distension in left iliac fossa.

Case 10.—Female, 19 years. General peritonitis three years ago; always constipated since then; also attacks of pain in left iliac fossa. During attacks constipation is accentuated.

Case 11.—Female, 61 years. Attacks of pain with local distension in left iliac fossa, followed by watery diarrhoea and sometimes by dark red haemorrhage.

Case 12.—Male, 63 years. Attacks of pain and local distension in left iliac fossa, followed by watery, sometimes blood-stained, diarrhoea.

In each of the above cases a potential volvulus of the pelvic colon was demonstrated by air-and-barium filling, except in Case 12, in which the pelvic colon proper was unusually short, but the iliac colon was redundant with a loop in the form of a U with closely approximated limbs. In this case torsion of the colonic mucous folds was also seen.

CONCLUSIONS

The study of the cases enumerated above has convinced us that recurrent sigmoid volvulus, far from being a mere curiosity, is a frequent source of obscure symptoms, which may prevent the patient leading anything like a normal, useful life. We do not wish to claim for this lesion an unduly prominent place, and by no means do we underestimate the important parts played by infective and by neuropathic elements in the genesis of abdominal symptoms. We feel, nevertheless, that this anatomical factor has been to some extent overlooked in the search for the solution of intestinal problems, and that this neglect is responsible for an appreciable number of diagnostic errors, with resulting therapeutic failure. We have endeavoured to show that the correct interpretation of these cases depends on correlating or, one might say, in bridging the gap between the clinical history and the radiographic signs elicited by the application of Fischer's method. In the three patients in whom this diagnosis was followed by operative intervention our diagnosis was confirmed by a complete disappearance of symptoms, and by the restoration of an invalid patient to a normal life.

The diagnosis made, the question of treatment arises. The gratifying results following excision of the redundant loop have confirmed us in the opinion that this is the method of choice. Cases are, of course, encountered in which, for one reason or another, this operation is contra-indicated. In such instances an attempt should be made to relieve the symptoms by fixation of the loop, while in those patients who are obviously bad surgical risks recourse must be had to such methods as colonic lavage and mild aperients, with avoidance of violent purgatives and physical strain, and the adoption of a diet in which the indigestible residue is reduced to a minimum.

A CASE OF OSTEITIS DEFORMANS TREATED WITH PARATHORMONE

BY

G. H. COLT, F.R.C.S.

SURGEON, ABERDEEN ROYAL INFIRMARY

AND

A. LYALL, M.D., M.R.C.P.

LECTURER IN CLINICAL CHEMISTRY, ABERDEEN UNIVERSITY

(With Special Plate)

The great impetus that has been given in recent years to the study of skeletal disease by the isolation of the parathyroid hormone by Collip, and by the recognition of the hyperparathyroid syndrome, has drawn renewed attention to a wider field in the pathology of diseases of bone. Numerous experimental studies in calcium and phosphorus balance and in blood chemistry have added to existing knowledge, and a new conception of bone pathology is taking shape. So far, however, the aetiology of osteitis deformans has escaped detection. It would seem clear from the investigations of several workers that, whatever be the true pathogenesis of this disease, the end-result is a gradual accumulation of calcium and phosphorus in the thickened and deformed bones. This is particularly true in the later stage. Thus, in the case investigated by Cuthbertson,[1] there was a daily retention of 0.4 gram calcium oxide and 0.2 gram phosphorus pentoxide, and in the metabolic experiment carried out by Rabinowitch[2] on a well-developed case, calcium and phosphorus retentions of 40 and 36.3 per cent. respectively were found.

When the patient whose record is given below came under observation in 1931, it appeared to us that the administration of parathormone might cause mobilization of the stores of calcium and phosphorus in the bones, and might relieve symptoms. We were particularly anxious to decrease the size of the cranium and face, and prevent, if possible, further implication of the cranial nerves. The effect of parathormone was reinforced by the administration of acid sodium phosphate by mouth.

CASE HISTORY

A married woman, aged 54 years, was admitted to the Aberdeen Royal Infirmary on February 28th, 1931, suffering from a fracture of the right femur caused by a fall when lifting a tub. The fracture was at the junction of the upper and middle thirds of the shaft. It was reduced, and skeletal traction applied. By May 17th the patient was walking with a calliper splint, and there was a firm union of fragments. The patient had been a healthy woman until the age of 31 years. She had one child, a daughter, in good health. The family history revealed no data of value. She had suffered from uterine haemorrhage in 1908, and states that both ovaries were removed for cysts. There are no notes available of the operation. The monthly periods continued for ten years after this. About 1920 she had attacks of abdominal pain after food, and the appendix was removed. In 1922 she fractured the right tibia by a fall. There was no evidence, in the notes relating to the case at that time, of any generalized bone disease. About 1923 she noticed that her head was *increasing* in size and, in particular, that the forehead was becoming broad. She complained of headaches and numbness over the right side of the face, and deafness in the right ear. The bony deformity of the skull gradually increased. The photographs show the patient in 1906 (Fig. 1 on Plate) and in 1931 (Figs. 2 and 3).

Findings

Upon examination in 1931 the skull was found to measure 26½ inches in circumference, 14 inches over the vertex from pinna to pinna, and 17 inches from atlanto-axial joint to nasion. By radiological examination the calvaria was seen to be thickened, and showed patchy ossification. The pelvis showed the same appearances, and the shaft of the right tibia

was enlarged and thickened, and showed some cyst formation. A metal pin was *in situ* through the old fracture of the bone, which was not tender. The eighth left rib was thickened in its whole length. There was no deformity of the humerus, radius, ulna, scapula, sternum, clavicle, or other ribs. There was no gross abnormality of the heart and lungs. The blood pressure was 150/94. The blood count showed no anaemia and no abnormal cells. The Wassermann reaction was negative on several occasions. The urine contained no abnormal constituent. On vaginal examination no abnormality could be discovered. The muscular power in the arms and legs was fairly good, and the limb reflexes were present and equal. The plantar reflexes were flexor. There was no loss of skin sensation. The pupils reacted sluggishly to light and on accommodation. The eye movements were full, and no nystagmus was present. The fields of vision showed temporal contraction for white, and in the right eye a marked contraction for red. The optic disks were much cupped, and the right somewhat paler than the left. There were some unusual bands of optic atrophy radial in the optic disk. Left facial paralysis was present and an intermittent tic of the right facial muscles. The tongue was protruded in the mid-line, and the palate moved normally. Bilateral nerve deafness was present, the hearing being slightly more acute in the left ear.

The blood chemistry showed the following values in milligrams per cent.:

Date	Phosphate	Calcium	Sugar	Urea
10/9/31	2.0	10.0	—	—
2/12/31	—	11.0	—	—
30/1/33	4.8	9.3	81	32
3/2/33	4.5	9.4	—	—
8/3/33	4.4	10.0	—	—

The plasma phosphatase was 3.96 units.

Treatment

The administration of parathyroid extract (Collip) was commenced in March, 1931, and has been continued in dosage of from 5 to 10 units daily, with periods of intermission, during the past two years. Acid sodium phosphate, 30 grains, taken three times daily, well diluted in water, was given as an adjuvant to depress the absorption of calcium in the intestine, decrease the serum content in calcium, and promote the excretion of calcium in the urine. Sodium phosphate alone was found to be effective by one of us in the mobilization of calcium deposits in a case of calcinosis.[3] We had no facilities for estimating the effect of parathormone treatment by a balance experiment, but comparison of a series of *x*-ray films of the head suggests that there is now less calcification present in the skull than there was two years ago. We are supported in this by the opinion of Dr. Middleton Connon, honorary radiologist to the Royal Infirmary. The skull measurement has probably not increased. In 1926 the circumference of the head measured 25½ inches; in 1927, 25¾ inches; in 1930, 26½ inches; and in February, 1931, 26¼ inches. Six months after treatment was commenced the head measured 25¼ inches. Such measurements are subject to a certain amount of error.

The following measurements were made by Professor Alexander Low on January 27th, 1933:

Cranial circumference	678 mm.*	Face length	110 mm.
Nasio-inional arc ...	416 ,,	Face breadth	145 ,,
Nasio-inional chord ...	211 ,,	Interocular breadth ...	39 ,,
Cranial length	225 ,,	Bigonial breadth ...	101 ,,
Cranial breadth ...	190 ,,	Height standing ...	1,537 ,,
Cranial height	142 ,,	Span of arms ...	1,646 ,,

* 26.4 inches.

These measurements, contrasted with the average figures for a female, show that the cranial circumference is increased by at least 100 mm., the cranial length by 40 mm., the cranial breadth by 45 mm., and the face breadth by 20 mm. On the other hand, the face length and bigonial breadth are not increased. The breadth of skull in proportion to length is relatively great, so that the cranial index is 84.4—that is, brachycephalic.

The patient herself claims to have felt better during the past two years, and has been able to carry out her housework and go out walking without fatigue, which had not been the case before treatment. Her general appearance is markedly better. No renal calculus is to be seen on *x*-ray examination.

COMMENTARY

It is interesting to note the effect of parathyroid administration on the callus formation and consolidation during the healing of the fracture of the femur (Fig. 6). Consolidation was rapid, and the repair of the fracture ran a normal course. There has been no yielding of the bone at the site of the fracture since. Hueper[4] found that parathyroid administration increased the rate of calcification of fractures in animals by from 20 to 35 per cent., and Ross[5] noted that partial removal of the parathyroids resulted in delay in the union of fractures in experimental animals. If attention is directed to one particular area of diseased bone, and the penetration factors in the *x*-ray examinations are carefully controlled, it may also be possible to see if the pathological changes in the tissues of the bone are influenced by the removal of calcium and phosphorus.

Although parathormone has been used therapeutically in the present case, it is not claimed that osteitis deformans is associated with hypoparathyroidism. In this case the serum calcium has been within normal limits. This is in accord with the findings of O'Reilly and Race[6] in the investigation of a series of twenty-one cases of varying severity, where the serum calcium lay between 9.5 and 10.6 mg. per cent. Nor would parathyroid treatment be rational in all stages of the disease, since at the onset there may be increased excretion of calcium. But where excessive storage of calcium and phosphorus is occurring it may be possible to keep it in check by the mobilization and excretion of part of the accumulated stores.

SUMMARY

A case of osteitis deformans is described.

The effect of treatment with parathormone is discussed.

We have to thank Dr. Middleton Connon for his unremitting attention in obtaining a large series of films of the skull and fractures taken with comparable exposures; Professor Alexander Low of the anatomy department, Aberdeen University, for his careful measurements of the skull; and Dr. W. Clark Souter for his ophthalmological reports on the case.

A CASE OF MULTIPLE GASTRIC ULCERS

BY

A. WILFRID ADAMS, M.S., F.R.C.S.

SENIOR ASSISTANT SURGEON, BRISTOL ROYAL INFIRMARY

(With Special Plate)

A disease of such widespread interest as peptic ulcer appeals alike to the physician and the surgeon. When manifested in the very menacing form illustrated by the following case it demands extra respect, and seems to call for a special communication.

CASE REPORT

E. B., a man aged 30 years, was sent up by Dr. G. L. Ormerod of Westbury-on-Trym. For about four years epigastric pain had ensued after meals and was often relieved by vomiting. During recent months the trouble was accentuated and much weight had been lost. The patient's appearance accorded with the history and he was an unfavourable subject for major surgery. The pulse and temperature were normal, and the Wassermann reaction negative.

Slight exophthalmos was present. On December 7th, 1932, *five-sixths of his* capacious stomach and a large cluster of *lymph glands*, one of which was the size of a walnut, were removed. Inspection of the mucosal aspect of the resected portion showed four ulcer craters along the lesser curve, varying in diameter from about one to two centimetres; closer examination revealed two scars of former ulcers. The open end of the duodenum was closed, and the jejunum joined to the residue of the stomach, after the method of Polya. Healing was by first intention. He now looks well, eats a suitable diet, and remains free from all gastric symptoms. His weight was steadily increasing on May 10th, 1933.

COMMENTARY

Owing to the infrequent occurrence of multiple gastric ulcers there is a paucity of literature on the subject, but I have extracted a few illuminating facts, which are incorporated in the following observations.

Clinical: The history and findings of my case were those of an ordinary solitary peptic ulcer, and were in no way commensurate with the multiplicity of the lesions. This corroborates the evidence of Judd and Proctor[1] in a series of cases recently reported from the Mayo Clinic. *Radiology:* After an opaque meal there were visible three excrescences on the stomach shadow near the distal end of the lesser curvature (see Special Plate). These indications of ulcer craters are seen to correspond to the defects in the lining of the ablated organ. For this invaluable evidence I have to thank Dr. Mayes. It is highly interesting and significant to note, from Judd and Proctor's report, that in only two cases of their series did the *x*-ray examination reveal definitely two ulcers in the stomach. *Morbid anatomy:* The outstanding interest of the case of E. B. lies in the great rarity of such multiplicity of chronic ulcers as his stomach exhibits. Four craters are obvious, and small scars of former ulcers are visible on careful inspection. They lie, as in a chain, along the lesser curvature (see Special Plate). The occurrence of acute perforation was a not unlikely complication to expect in the case, for the stomach was not adherent. The exceptional swelling of the adjacent lymph glands in the lesser omentum bore eloquent testimony to the intense activity of the pathological process. Mr. A. D. Fraser has kindly verified the simple character of the condition in his histological report: "Simple peptic ulcers—no evidence of malignancy."

Number of Ulcers: Judd and Proctor analysed 1,475 cases of gastric ulcer operated on in the Mayo Clinic from 1914 to 1924. Of this total there were eighty-seven with two or more ulcerations in the stomach—that is, 6 per cent. Only about fifteen times in the vast array of nearly 1,500 cases were more than three ulcers present. Portis and Portis[2] quote Fenwick's search of post-mortem records, in which he found *867 cases of two or more* ulcers reported in 19.5 per cent., four or more ulcers in thirty-seven cases—that is, 4.2 per cent. These were all cases with active or open ulcers. A comparison of these figures suggests that the actual proportion of multiple to solitary gastric ulcers is well over the number met with surgically. The disparity is, perhaps, due to the different social categories from which the two sets of figures were collected. The Mayo Clinic draws its patients from a class which takes earlier and more notice of disease. *Site:* The situation of the lesions in the multiple as in the solitary ulcers reveals a predilection for the lesser curvature. This is demonstrated remarkably in the specimen here reported. *Associated disease:* The association of syphilis with multiple ulceration is slight, according to Judd and Proctor's findings. They report only six such cases in their series. The remainder of their cases were of a simple nature, apart from two. Cancer was definitely present among the ulcers of two cases, and was indefinitely diagnosed in three others. *Liability to acute perforation:* Instances of this complication figure relatively more prominently in the literature. Perhaps it is the more dramatic character of the symptoms and pathology of the acutely perforating ulcers that explains this distinction. Julian Taylor[3] reported perforation of peptic ulcers; Skemp and Skemp[4] and Drury[5] report multiple perforated gastric ulcers, as do Masson and Simon.[6]

In the present case such diffuse ulceration, with the dangers of blood vessel erosion, perforation, and malignant transformation multiplied proportionately, justified surgical measures of corresponding magnitude. The extensive resection which was undertaken has been well justified by the sequel. Once again the experience of this case corresponds with the main findings of Judd and Proctor, who report that some form of resection was performed in the majority of their series of cases. The hospital mortality was notably low—3.4 per cent.

CHRONIC PERFORATING ULCERATION OF THE FOOT

OBSERVATIONS ON A CASE TREATED BY LUMBAR SYMPATHECTOMY

BY

T. G. ILLTYD JAMES, F.R.C.S.

AND

NORMAN M. MATHESON, F.R.C.S.

CENTRAL MIDDLESEX COUNTY HOSPITAL, LONDON

(With Special Plate)

W. Mayo[1] has pointed out that negative and positive results are necessary in assessing the value of any therapeutic measure, and nowhere is this better illustrated than in the surgery of the sympathetic nervous system. The observations made in the following case may therefore be of interest.

C. W., a male aged 56, was admitted to hospital in March, 1932, with ulcers of the left foot, which had been present for a period of three years. He had been treated on many occasions, but the ulcers were constantly breaking down. He had been under treatment in this hospital two years previously, and, with rest in bed and palliative measures over the long period of six months, the ulcers healed, but broke down again on the resumption of activity. The big toe of the left foot had been amputated some years before, for a condition the nature of which could not be definitely ascertained, *but which* appeared to be a hallux valgus with ulceration. On examination three perforating ulcers were found on the sole of the left foot, two situated anteriorly on the under aspect of the fourth and fifth metatarso-phalangeal joints, and one on the under aspect of the heel (see Special Plate, Fig. 1). The latter was more superficial, but the other two were about three-eighths and one-quarter of an inch deep respectively, and surrounded by a ring of heaped-up white skin. The margins were hard, and the callosity extended for about an inch around the ulcers. The discharge from the ulcers was thin and watery. Although the ulcers were deep, *x* rays revealed no abnormality in the underlying bones. The arteries of the limb appeared normal. The Wassermann reaction was

negative, and general examination, including a careful investigation of the nervous system, was also negative. Each foot showed a slight degree of pes cavus. There was no clinical or *x*-ray evidence of spina bifida occulta, or of any other lesion that might have a bearing on the aetiology.

Palliative treatment was adopted for four weeks, with complete rest in bed. There was no improvement in the local condition. The patient's incapacity for work, owing to constant attention to the ulcers, made other treatment desirable. Periarterial sympathectomy of the femoral artery having proved of uncertain value in other lesions, it was thought that neurectomy of the left lumbar sympathetic, with consequent permanent vaso-dilatation (or at least vaso-dilatation of prolonged duration), would be likely to lead to some nutritional improvement with permanent healing. The operation was performed on April 23rd, 1932. The left lumbar chain was exposed through the peritoneal cavity, and the portion of the sympathetic cord from just below the fourth ganglion, up to and including the second lumbar ganglion, was removed.

Following operation the usual effects were observed in the affected limb—increased temperature, increased warmth, absence of sweating, and dryness of the skin. An improvement in the appearance of the ulcers was noted six days after the operation. The surrounding skin appeared less hard, and the discharge from the ulcers was definitely increased, although it was still thin and watery. On May 20th, about four weeks after the operation, the ulcers were much smaller (see Special Plate, Fig. 2), and one week later almost healed. Healing was complete six weeks after the operation (see Special Plate, Fig. 3). The healed areas became firmer, and remained healed for a period of two months, when both anterior ulcers again broke down. Four days after operation the patient complained of an induration which he felt in the glans penis. This had not been noticed by the patient before operation. Examination showed an indurated area on the right side of the glans the size of a threepenny piece. The area was not ulcerated. Two months later the indurated area on the penis had become ulcerated. The lesion suggested a syphilitic origin, either a primary or a recurrent chancre, but Wassermann tests, before and after a provocative dose of N.A.B., were negative. A section of the edge of the ulcer was taken, and microscopical examination revealed the appearance of a typical squamous carcinoma (see Special Plate, Fig. 4).

COMMENTARY

From these observations it will be seen that, while healing was rapid after the improvement in the circulation to the foot, the vascular changes, although persisting, were not sufficient to maintain healing. In this type of ulceration there is some factor at work which causes repeated breakdown, despite even the maximum effects that can be produced by sympathetic denervation. Although the onset of carcinoma in this case must at present be regarded as a coincidence, it may be noted in view of the increasing number of operations performed on the sympathetic nervous system. The surgery of this system is still in its infancy, and any unusual feature is worthy of record.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

A CASE OF DIAPHRAGMATIC HERNIA

(With Special Plate)

In view of the unusual position of the hernial orifice the following case appears to be worth recording.

A male child, aged 2 months, was attending the orthopaedic out-patient department of the Croydon General Hospital in December, 1932, on account of a talipes equino-varus. While waiting to be seen the mother fed it, and, soon after, it had a convulsion and ceased breathing. After artificial respiration it recovered, and was admitted to the hospital. The mother gave a history of similar attacks before, which had been less severe. On examination the child looked extremely ill. Respiration was laboured, and about 40 a minute; the temperature was 98.2° F., the pulse feeble at 160. The apex beat was in the anterior axillary line, but little else could be made out, as any movement of the child seriously embarrassed respiration. It died twenty-four hours later, no diagnosis having been made. A post-mortem examination revealed the following condition. The peritoneal cavity was almost entirely occupied by a large liver and a greatly distended stomach. Save for six inches of jejunum, all the small intestine, caecum, and ascending and transverse colon had herniated through the right side of the diaphragm. The intestine returned to the abdomen near the splenic flexure. Only a small portion of the right lung was visible at the apex, the heart was displaced well over to the left, and only a small portion of the left lung could be seen. No definite peritoneal sac could be seen round the hernial contents. The case appeared so interesting that a flash-light photograph was taken before the viscera were disturbed.

The hernial orifice had apparently resulted from a lack of fusion of the splanchnic mesoderm and the right pleuro-peritoneal fold. Such a hernia is much commoner on the left side, according to the literature on the subject. It is interesting to speculate whether artificial respiration would have further reduced the hernia.

We are indebted to Dr. Genge for permission to publish this case.

Gillingham, Kent.

A CASE OF DIAPHRAGMATIC HERNIA

The following case appears to be of sufficient rarity to merit description.

A Somali, male, aged about 25, was admitted to the Burao Hospital on December 25th, 1932, giving the following history. About seven years previously he had had an attack of what he thought was pneumonia. Apart from that he had kept in perfect health until just over a year before admission, when, in a fight, he was struck by a stick on the upper part of the chest. This caused some localized swelling, which subsided in a few days. No history of any wrench or strain could be obtained. There were apparently no further symptoms until a month before admission, when he began to get some colicky pain, and to notice a lump in the abdomen. The bowels were constipated, but there was no vomiting and no urinary symptom.

On admission the patient was a well-nourished young man, and he did not appear to be very ill. The abdomen was flaccid, and on the right side there was a large, hard, freely movable tumour, extending from the right iliac fossa upward to about the level of the umbilicus. Rectal examination and examination of the blood and urine were negative. An enema gave a good result, and did not affect the size of the tumour. No *x* rays were available. The tumour was thought to be of either caecal or renal origin. Operation was advised, but not regarded as urgent. On December 31st his condition suddenly became worse, and it was obvious that he had a general peritonitis, a tympanitic, immovable, tender abdomen, and a pulse of 130. An enema still gave a good result. Operation was now urged, but refused. The patient died during the night.

Post-mortem examination showed a general peritonitis. The caecum was distended with hard faeces to the size of a small coco-nut, and its anterior wall showed several greyish gangrenous patches, one of which had perforated and caused the peritonitis. Numerous stercoral ulcers were found in the mucous membrane. The ascending colon was distended with hard faeces to the diameter of about two inches. The transverse and descending colons were almost empty. On opening the chest the hepatic flexure was found protruding through the right side of the diaphragm as a small loop, measuring about three inches on its convexity. It was flaccid, healthy, and showed no sign of strangulation. It was contained in a hernial sac of diaphragmatic pleura. There was no peritoneal covering.

Death was due to perforation of a stercoral ulcer of the caecum, the result of chronic intestinal obstruction from a diaphragmatic hernia, and the cause of general peritonitis.

Diaphragmatic herniae are of considerable rarity, and the majority of cases have been in infants, born dead, or dying soon after birth. Few of the congenital cases can survive to adult life, at any rate without symptoms, and most cases in adults are due to injuries to the diaphragm. In the case described above there is no history of any injury which could involve the diaphragm, and the presumption is that the hernia was a congenital one. There was certainly no penetrating wound, and apparently no wrench or strain which could have affected the diaphragm.

I am indebted to Dr. A. W. H. Donaldson, medical officer in charge, British Somaliland, for permission to publish this case.

A. H. MORLEY,
East African Medical Service.

Reports of Societies

ENTAMOEBA HISTOLYTICA CARRIERS

At the annual general meeting of the Royal Society of Tropical Medicine and Hygiene the retiring president, Dr. G. Carmichael Low, welcomed the new president, Sir Leonard Rogers. Subsequently Professor Gordon Thomson received the Chalmers medal on behalf of Dr. Adler.

A paper by Colonel H. W. ACTON, on *Entamoeba histolytica* carriers and their treatment, was read by Dr. D. PANJA. Acute amoebic dysentery was estimated to occur only in about 5 per cent. of cases of amoebic colitis in an ordinary well-fed population, but its incidence might rise to 25 per cent. following malnutrition or intercurrent disease. As a rule the lesions in the bowel were trivial, producing at first constipation, which later might alternate with diarrhoea; sometimes morning diarrhoea with mucoid stools resulted. This was the picture in the common type of carrier. *E. histolytica* could live a purely coprozoic life in the colon without producing bowel lesions; two necropsies on amoebic carriers were cited in support of this view. Factors that permitted penetration of the healthy columnar cells included superficial trauma induced by either helminths or dysentery bacilli. As stasis continued the bacterial flora changed, streptococci replacing coliform organisms; the more numerous these streptococci colonies on culture, the more extensive the ulceration of the gut. In the mixed type of bacillary and amoebic carrier, a varying number of non-lactose-fermenting colonies might be seen; they included typical dysentery bacilli, *Bacillus pseudo-carolinus*, and *B. morganus*, as well as late lactose-fermenters such as the meta-dysentery group. Three different types of carriers were recognizable: (1) Coprozoic carriers, who showed neither symptoms nor lesions. (2) Pathogenic carriers, who had pathological lesions and slight symptoms. Here a breaking-down of the local defences in the base of the ulcer resulted in embolic manifestations such as sciatica, myositis, arthritis, or even myocarditis, and haemolytic streptococci were often found in the urine. Symptoms due to stasis followed: these included dysfunction of the thyroid and adrenals, with harsh cold skin and low blood pressure. Leucodermia, food idiosyncrasy, urticaria, eczema rubra, and asthma might also be encountered. (3) Mixed carriers of amoebic and bacillary infection constituted about 15 per cent. of the Calcutta cases, and they were difficult to cure with either emetine or bismuth emetine iodide alone. Reflex spasms at the pylorus, caecum, and transverse and descending colon occurred; a few developed signs of duodenitis and duodenal ulcer. The invading Gram-negative bacilli from these ulcers—for example, *B. asiaticus*—did not cause emboli, but occasionally gave rise to continued fever. More commonly, such organisms were excreted in the bile or in the urine, when they might produce cystitis. Routine treatment consisted of 1/6 grain of omnopon (Roche) at night, followed one hour later by 2 grains of bismuth emetine iodide in 1 oz. of paraffin. This was continued for twelve nights, the stools being subsequently examined for cysts on six consecutive days. About 5 to 8 per cent. failed to be cured, mostly owing to concomitant bacillary infection. Mixed infections in addition were treated with a vaccine prepared from the causative organism, and with 10 grains of calcium lactate and 1/4 grain of parathyroid night and morning, while starches were eliminated from the diet. Bismuth kurchi bark and carbasone had recently been tried with promising results, both methods being very effective without producing toxic symptoms.

Professor WARRINGTON YORKE, in opening the discussion, said the immediate symptoms in amoebic dysentery were readily cleared up; the difficult thing was to produce permanent sterilization. In following up cases the real issue was not what happened up to nine days subsequent to treatment, but what took place after nine months. Another point of interest was why infected people in England and other temperate zones failed to develop symptoms yet did so on proceeding to the Tropics. It would appear that some concurrent infection must be necessary. Dr. CARMICHAEL LOW doubted whether the symptomless carrier had lesions in the bowel. He mentioned the case of a patient dying of liver abscess in whom he had failed to find bowel lesions at necropsy, despite having examined every inch of the bowel. He agreed with Professor Yorke that cases should be examined over longer periods, at least for twenty-one days. Professor GORDON THOMSON cited Sellards's experiment as evidence against the coprozoic or contact carrier, the difference between the symptomless carrier and the case with clinical manifestations, in his opinion, depending on host resistance. To exclude invasion of the gut in the contact carrier it would be necessary for serial sections to be cut throughout the colon.

Dr. C. M. WENYON agreed with Professor Thomson as to the difficulty of excluding lesions in the gut in contact carriers. Certainly naked-eye examination was not enough, as was shown in the section of a very small ulcer which he (Dr. Wenyon) had put out for inspection and which had been found by accident. He agreed with other speakers that six days was a quite inadequate time in which to estimate whether infection had been eradicated, but in Calcutta reinfection might continually be taking place, so it was probably not worth while prolonging observations. Dr. MANSON-BAHR agreed with Dr. Wenyon about the minute nature of bowel lesions which were frequently revealed in life during sigmoidoscopy, especially if a magnifying attachment was used. He did not think haemolytic streptococci had any significance in amoebic colitis, and estimated that the patient should be watched for at least two years before deciding whether he was cured. The immediate success of treatment could best be gauged by periodical sigmoidoscopic examinations. Sir ALDO CASTELLANI agreed with Colonel Acton that mixed carriers occurred, and that though Shiga and Flexner bacilli were rarely isolated meta-dysentery bacilli were common. He advocated vaccines in these cases.

Dr. HAMILTON FAIRLEY pointed out that in many symptomless carriers the sigmoidoscopic appearances of the bowel were absolutely normal, and there was neither pathological exudate nor occult blood in the faeces. Evidence that the gut wall was invariably invaded was still inconclusive, and more pathological data on the carrier state were necessary before the question could be considered settled. He did not regard *Bacillus pseudo-carolinus* and meta-dysentery organisms as pathogenic, while metastatic complications due to streptococci were in his experience rare. Captain D. D. LAMBERT pointed out that as about 50 per cent. of the people resident in Calcutta were cyst carriers, such conditions as constipation, fibrositis, and the various clinical syndromes described were probably fortuitous associations with the *E. histolytica* carrier.

Sir LEONARD ROGERS stressed the difficulty of keeping patients long under observation in Indian hospitals, and agreed that trauma of the mucosa induced by ankylostomes would favour amoebic invasion and so explain the greater frequency of bowel lesions in the Tropics. In amoebic abscess of the liver scars or actual ulcers were present in the caecum in forty-nine out of fifty of his cases.

Reviews

GENETICAL SCIENCE

The unique place which the science of genetics holds in the public mind is due to the direct and tangible nature of its appeal to human interests, and also to the fact that its technicalities are relatively simple and easily grasped by the non-specialist. Furthermore, as Dr. C. C. HURST explains in his latest book, *The Mechanism of Creative Evolution*[1], it provides a most satisfactory account of a mechanism through the functioning of which evolution has proceeded. The gene rather than the cell has come to be regarded as the ultimate unit of life, and therefore is the necessary and ultimate basis for the creation of new species. In this book, which indeed is a most magnificent specimen of the publisher's art, the whole achievement of genetical science through its thirty years of experimentation is admirably presented. The principles of Mendelism are set forth with economy and precision. It shows how, in the early days immediately following the rediscovery of Mendelism, the enthusiasm of a small group labouring in a special field led to an isolation which favoured the development of simply and clearly defined concepts, and also to the development of routines of procedure which tended towards eventual stagnation. Next it is shown that from this stagnation genetics was rescued through its contacts with cytology. It was found that genetic phenomena could be referred to, and had to be explained by, corresponding cytological phenomena. A comprehensive survey of the results of genetical and cytological inquiry leads into attractive fields of interpretation and speculation which render this book both enjoyable and stimulating.

THE STREPTOCOCCUS

From the standpoint of human pathology the streptococci constitute one of the most important genera. Not only are they responsible for an enormous amount of disease, but the body's defences seem ill designed to meet their onslaught, and one encounter with them only too commonly leaves behind it permanent damage and a heightened susceptibility rather than an immunity. Our knowledge of the streptococci has not advanced as rapidly as in the case of some of the other pathogenic bacteria. They are elusive subjects to study, and their instability has rendered their classification a matter of supreme difficulty. During the last few years, however, considerable progress has been made in unravelling some of the problems connected with these micro-organisms, and the time is opportune for a review of the situation. It is for this reason that we welcome Dr. ANNA W. WILLIAMS'S monograph entitled *Streptococci in Relation to Man in Health and Disease*.[2]

Dr. Williams is entitled to speak with authority on this subject, for she has made it one of special study. Her monograph is not a colossal compendium of the literature, but a broad review of the subject in which the points of practical importance are not buried in a welter of facts. Opening with an historical sketch and a general classification in the first chapter, the author considers in turn the general characteristics of streptococci, their incidence and their effect on man, and streptococci in local infections. Elective localization is treated in an eminently sound and well-balanced manner, and in the discussion of local immunity due prominence is given to the excellent work of Gay on the part played by the cells of the reticulo-endothelial system in this respect. Chapter IV concerns streptococci in general infections, and following this are chapters devoted to erysipelas, scarlet fever, and septic sore throat. No doubt Dr. Williams is right in stressing the need and value of antibacterial serums—anti-endotoxic serums, to use her terminology—in combating infections due to haemolytic streptococci whose production of exotoxin is of a low grade, but not everyone will agree with the statement that scarlet fever is the only condition in which antitoxic serum is of use. Chapter IX is devoted to the relation between the various haemolytic streptococci, a tentative classification being given, and following this is a discussion of that difficult question of the relation of streptococci to rheumatic fever, arthritis, and allied conditions. This latter account is clear and unbiased, though one wonders how far the statement that the removal of tonsils and adenoid tissue has been followed by a lower incidence of rheumatic fever is supported by clinical experience. The aetiological relation between streptococci and such diseases as measles, epidemic encephalitis, influenza, poliomyelitis, and the common cold—usually considered as virus diseases—is accorded a separate discussion. This question is treated conservatively, and rightly so, and the opinions expressed in it will meet with widespread agreement. General considerations bearing upon our knowledge of streptococci terminate this valuable monograph. It has a good bibliography and an adequate index.

HAEMATOLOGY

It seems to be the custom for university professors of medicine and physicians of medical schools to publish treatises on haematology for the use of their own pupils. The personal mutual understanding between pupil and teacher is always desirable. *Practical Hematological Diagnosis*,[3] by Professor O. H. PERRY PEPPER and Dr. DAVID L. FARLEY, is an example of this class of book. Simply written, and following well-beaten orthodox lines, it will prove a useful guide to knowledge of haematological methods and diagnosis. In a future edition the authors should study compression—by deleting references to discarded methods and views, and by removing the frequent repetitions and redundancies, which are tiresome and only serve to swell the size of this volume. We do not need to be told at page 312 that evidence of blood regeneration is shown " by the presence of nucleated red cells and the increase in the reticulocytes." This has already been told in previous pages, and is a haematological commonplace. Generally, perhaps wisely, the authors are afraid of dogmatizing, and personal views are disappointingly absent or vaguely expressed. The uses of the haematocrit are strongly advocated ; it is admittedly an easy and rapid method for estimating roughly the blood cell volume, but the values obtained must of course be qualified by the degree of variability in size of individual cells. A similar qualification is necessary with the use of refractometers, which also measure blood cells in mass, and do not, as stated on page 55, measure single cells. The authors most justly have a lack of confidence in haemoglobinometers ; they agree that determination of oxygen capacity by the Haldane-Van Slyke method is best, but not practical for clinical application No mention, however, is made of Haldane's haemoglobinometer so much in use in this country. The expression of Hb in grams is difficult for those who are more familiar with percentage values. The old estimation of 5,000,000 per

[3] *Practical Hematological Diagnosis.* By O. H. Perry Pepper, M.D., and D. L. Farley, M.D. Philadelphia and London: W. B. Saunders Company. 1933. (Pp. 582, illustrated. 30s. net.)

c.mm. as the number of red cells in normal blood is maintained in spite of recent observations by Osgood and others that the mean normal value is much greater than this; the limits for normal colour index now accepted are 0.84 to 1.11. The statement on page 351 that acute poisoning by carbon monoxide gas "changes the haemoglobin to methaemoglobin" is not correct, and should read "carboxy-haemoglobin." Much of Part III is of the nature of a catalogue to be used for reference; the footnotes will be very helpful for this purpose.

Those who need to economize time will welcome *General and Child Haematology*,[4] by Dr. W. M. FELDMAN, one of the Pocket Monographs on Practical Medicine series. The title is rather ambitious. It is a comprehensive collection of generally accepted statements about the blood, shortly and clearly expressed, and unencumbered by descriptions of methods or apparatus employed in blood examinations. The section on blood diseases is necessarily limited by space. The clinical haematology of Addison's anaemia and the effect of liver treatment in this disease are not described, probably because this is not a blood condition met with in children. The chapter on blood groups, dealing with the requirements of transfusion and with social and biological interests, are useful, though students of the subject will consult more extended treatises. This is a compact vade-mecum which will probably help the busy physician.

THE SOCIAL SERVICES

We have a remarkable book in *British Social Services: the Nation's Appeal to the Housewife and Her Response*.[5] It is by the Rev. J. C. PRINGLE. Those who are acquainted with the author's work as secretary of the London Charity Organization Society and rector of St. George's-in-the-East will not need the assurance given by Sir Charles Mallet in his "Foreword" that "it is packed full of practical and first-hand knowledge, based on continuous and sympathetic observation of the daily lives of working people," and that the pronouncements it contains are "both fearless and vivacious." To the less informed prospective reader this assurance can be renewed and the epithets confirmed. The book is the acceptance of a challenge, and the greater part of it is itself a challenge. At an international congress on social work in Frankfort last year Professor Gösta Bagge of Stockholm declared that "the decline in the feeling of personal responsibility and the extension of public relief" threatens the existence of modern society, that "complete reorganization and reform of present social policy can alone avert impending disaster," and that what is needed is "a characteristic criticism based on popular psychology . . . and a social policy inspired thereby." Such a criticism and the basis of such a policy are what Mr. Pringle sets out to supply and establish. He offers a forceful and thought-provoking challenge in defence of a position which has not recently been very popular in the field of social work in general, and which has been assumed by many people to be no longer tenable.

Mr. Pringle's thesis may be described as a development of the following propositions: (1) that the voluntary and individual supply of social needs is always and everywhere preferable to the compulsory and collective; (2) that the sympathetic and intelligent administration of the Poor Law is more effective for a large section of the people than even the best scheme for compulsory insurance; (3) that the family or household, and not the individual, must be taken as the essential economic unit, and that, within the family, it is the housewife and mother, and not the wage-earner, who should be regarded as of paramount importance; (4) that any successful efforts for promoting social welfare must be based upon an understanding of the psychology of the poor family and not upon a misunderstanding of its economics. The mere enunciation of such propositions by one of the most experienced of social welfare workers (though it should be said that the form in which they have just been stated is the reviewer's and not the author's) will itself be refreshing to many readers, and there is none but must be intrigued and interested by the vigour, ingenuity, and knowledge displayed in their support. Particularly will most medical readers be engaged by the way in which the author deals with some questions of national health insurance and with recent developments in public health services. Not everyone, even if he starts out free from socialistic or communistic bias, will be persuaded, but there is scarcely a page in the first 116 of Mr. Pringle's book which will not carry the conviction that he is displaying at any rate one aspect of the truth which must not be ignored.

Unfortunately after the eighth chapter there is a change. What has previously been a point of view becomes an obsession. The arguments and the principles advocated are applied to subjects and conditions which are not similar to those previously dealt with. The book loses its interest and effectiveness because it ceases to consist of arguments which, even if they be considered mistaken, have to be understood, weighed, and met, and becomes, for the most part, the vehicle for suggestions which the ordinary intelligent reader cannot regard seriously and can only smile at as extravagant or absurd.

SOME RECENT WORK IN PRACTICAL THERAPEUTICS

General Therapeutics,[6] by Drs. B. FANTUS and L. B. KARTOON, is a volume of the Practical Medicine Series of Year Books (series 1932). This book provides an account, with references, of some of the important advances in therapeutics made in 1932. The advertisement states that the authors give an account of 333 articles drawn from forty-two American, fourteen German, and six English, and various other journals. Inspection of the references shows that in fact about three-quarters of these are to American work. The volume therefore gives a partial rather than a general survey of recent advances in therapeutics. For example, no reference is made to any work on the new quinine substitutes plasmoquine and atebrin. Subject to this caveat regarding its restricted scope, the volume can be recommended to all who desire a short and readable summary of many of the important recent discoveries in practical therapeutics. The chief point that strikes the reader is the remarkable enterprise of American physicians and surgeons in applying advances in biochemistry and physiology to therapeutic purposes. The authors have shown good judgement in compiling their abstracts, for they give adequate details of all the work that they consider of sufficient importance to deserve mention. Moreover, they have included in their text reproductions of forty-two illustrations. The increase by geometrical progression of scientific literature is steadily increasing the difficulties of those who wish to keep in touch with important advances, and hence a critical and selective review of recent progress such as is furnished in this volume is extremely useful.

DRUG ADDICTION IN EGYPT

In the Treatment of Drug Addiction by Phlyctenotherapy[7] Dr. P. MODINOS of the European Hospital of Alexandria gives a short but graphic description of the chief forms of drug addiction. He mentions in particular the appalling ravages of this vice in Egypt and quotes the official estimate of 500,000 addicts, which represents 3.8 per cent. of the population. His special method of treatment "phlyctenotherapy" consists in the injection of blister fluid. A blister of some 10 sq. cm. is produced on the patient, which yields from 10 to 15 c.cm. of serum, and this is injected intramuscularly. This method, which is a form of autotherapy, the author has used since 1929 in the treatment of seventy-six cases of drug addiction. He claims thirty-two cures out of forty-three heroin addicts treated, which is a very remarkable result. Details are given regarding the history of twenty-four cases. The author quotes evidence regarding the success of his method in other Egyptian hospitals, in Bangkok, and in America.

Towards the close of his book Dr. Modinos discusses how the traffic in dangerous drugs can be controlled, and asks why Egypt should be more plagued with drug addiction than any other country in the world. He points out that a few years ago this vice was threatening the national life of Egypt. In 1930 the number of addicts was estimated at 500,000, while 10,000 convictions were obtained in the indigenous courts for drug trafficking; moreover, the hospitals and asylums were flooded with addicts seeking cure. He pays a high tribute to the work of Russell Pasha, who has produced an enormous improvement in the past two years, and also to the excellent work done by the League of Nations. In the final chapter there is an interesting discussion on whether in the case of cannabis indica it is better to attempt to abolish its use or to control its consumption by a Government monopoly, and the author decides in favour of the former mode of action.

Notes on Books

In this country we are often accused of not taking our play seriously, and if such a statement is open to correction we can at least claim that we do not take it so seriously as our friends in America. In *The Child and Play*[8] the earnest student of this subject will find nothing left unsaid on this question from the scientific aspect. The material is based on the reports of many committees and subcommittees which were considered at a conference on child health and protection in Washington in 1930, and it will appeal chiefly to those interested in education and child welfare.

In *Golf Made Easy*[9] Dr. FORREST returns again to the theme of his previous publications, *The Basis of the Golf Swing* and *The Golf Stroke*, in which we are encouraged to believe that the way to become scratch players is simple if we can only acquire the method of turning the hands at the right moment in the right way. With minute instructions and many excellent photographs this solution of all golfing ills is set forth, though the earnest seeker after truth will need no small amount of mental concentration to get full benefit from the work. Golfers are, however, notoriously the most optimistic of mankind (if we except entrants for the Irish sweepstakes), and many will be ready to sample this medicine, though the reviewer himself, stricken with disease long reckoned constitutional, is not too sanguine of a cure.

Mountains may seem as far removed from medical science as chalk from cheese, but since the *London Mercury* has devoted an editorial page to the review of a mousetrap, we feel it excusable to give a few lines to the recently published book, *Alps and Men*,[10] by G. R. DE BEER. Switzerland claims many friends in this country, both as a holiday ground and as a health resort. Those who love it and are interested in its history during the last 200 years will find plenty of entertainment in this work. It draws largely upon the diaries of famous travellers and tourists in the country from 1750 onwards—British aristocrats on the "grand tour," refugees from the French Revolution, generals, scientists, explorers, schoolmasters, poets, writers, and composers—even the famous Bishop of Derry and Earl of Bristol, to whose memory there is an "Hotel Bristol" in almost every city in Europe. Copious illustrations are provided, and the author, with his expert knowledge of the country, has succeeded in producing a pleasing volume.

The tenth volume (Scurvy–Pineal Gland) of the New German Dictionary of Practical Medicine,[11] edited by Professor GEORG KLEMPERER and the late Professor FELIX KLEMPERER, marks the conclusion of this monumental work, which began five years ago. Supplementary volumes, however, will be published at regular intervals. The tenth volume contains the following contributions by well-known writers: scurvy, by Professor W. Stepp and Dr. Voit of Breslau; scrofula, by Dr. K. Klinke of Breslau; parasitic stomatitis, by Professor A. Buschke and Dr. A. Joseph of Berlin; social hygiene, by Dr. A. Fischer of Carlsruhe; sporotrichosis, by Dr. A. Joseph; disorders of speech, by Professors E. Forster of Greiswald and T. S. Flatau of Berlin; sprue, by Professor C. Hegler of Hamburg; syphilis, by Professor Buschke and Dr. A. Joseph; syringomyelia, by Professor H. Schlesinger of Vienna; tabes, by Professor A. Goldscheider of Berlin; tetanus, by Professor H. Hetsch of Frankfurt; thymus, by Professor W. Berblinger of Jena; rabies, by Professor Hetsch; trauma as cause of internal diseases, by Professor R. Stern of Breslau; trichinosis, by Professor J. Bongert of Berlin; tropical diseases, by Professor P. Mühlens, Dr. E. G. Nauck, and Dr. Curt Sonnenschein of Hamburg; soft chancre, by Professor W. Frei of Berlin; uraemia, by Professors F. Volhard and E. Becher of Frankfurt; urticaria and Quincke's oedema, by Professor Hansen of Heidelberg; varicose veins, by Professor Baetzner of Berlin; dental diseases and internal medicine, by Professor J. Citron of Berlin; diseases of the teeth and jaws, by Professor G. Axhausen of Berlin; and the pineal gland (zirbel), by Professor Berblinger of Jena. A list of the contributors and a subject index are contained in a special volume.[12]

Not least among the activities of the Council for the Preservation of Rural England is the publication from time to time of literature which is designed both to further the principles for which the council stands and to draw public attention to the beauty and interest of the English countryside. Both these objects have been achieved in *The Penn Country of Buckinghamshire*[13]—issued by the Penn Country Branch—an attractive volume of 128 pages, with sixty-two illustrations, many of which have been specially produced and are of great charm. A foreword is supplied by the Prime Minister, whose home is in the heart of this country, and among the prominent contributors are Mr. G. K. Chesterton, Major Conings-by Disraeli (on Hughenden and Disraeli), the Hon Sir Frank MacKinnon, Mr. C. H. Biddulph-Pinchard, and Mr. Clough Williams-Ellis.

WHAT TROPICAL MEDICINE OWES TO ANIMAL EXPERIMENT

STEPHEN PAGET MEMORIAL LECTURE BY SIR LEONARD ROGERS

In connexion with the annual meeting of the Research Defence Society on June 22nd, with Lord LAMINGTON presiding, Sir LEONARD ROGERS lectured to a very large audience in the theatre of the London School of Hygiene and Tropical Medicine on "The Saving in Suffering of Man and Animals due to Medical and Veterinary Research, with Special Reference to the Tropics." The lecture was illustrated by lantern views.

Sir Leonard Rogers began by saying that the sufferings of animals, as well as of man, had been immensely reduced through animal experiment. This might safely be affirmed as the universal opinion of all the scientists who were best qualified to judge at the present day. It followed that if the opponents of research had succeeded in their long-sustained efforts to prevent such experiments they would have been guilty of the most appalling and wholesale cruelty, not only to mankind, but to the animals they professed to love. The saving of life and suffering due to physiological and therapeutic experimental research had been dealt with by previous Stephen Paget lecturers, but in no field had this been more conspicuous during the last three decades than in tropical diseases, and of the work in this field he proceeded to give a brief account.

Dealing first with snake bites, Sir Leonard Rogers said that all the essential knowledge of antidotes and treatment was due to animal experiments. Many years ago Calmette had made an anti-cobra serum which could neutralize the venom in the system, and save life if given in time. It became also known that permanganate of potash mixed with the venom of any snake rendered it inert, and Sir Lauder Brunton invented a small sheathed lancet with a compartment for permanganate for immediate use in the absence of serums, by incising the site of the bite. The Humane Act of 1876 prevented Sir Lauder from testing its practical value on animals, and it was not until 1903 that, at Sir Lauder's suggestion, the lecturer demonstrated its value by a few experiments, with the result that within two years he was able to record ten recoveries among twelve persons who had been bitten by deadly snakes. And what was the suffering inflicted in those few experiments? The few cats which were permitted to come round from the chloroform had very small wounds—of course, dressed antiseptically—and showed no evidence of pain. The only trouble he had was that several of them would come up to him to have their heads rubbed.

In the case of cholera, the most serious epidemic disease in India, the lecturer showed tables illustrating the striking reduction in case mortality among Calcutta hospital patients. This had been brought about by the use of intravenous injections of hypertonic and alkaline salines and the oral administration of permanganate pills. The clue to the use of permanganates was furnished by the snake venom work just mentioned, and he had been able to show by a few simple experiments on pigeons that small quantities of permanganate would neutralize the toxins of the cholera bacillus. He also showed the statistical results of the use of anti-cholera inoculation. A single dose of the present improved vaccines had afforded very valuable protection. In short, experimental research had offered the means of checking the spread of cholera and of treating effectually the sufferers from the disease. The virulent type of small-pox was now more prevalent in India than elsewhere, so that it might be looked upon as mainly a tropical disease. He showed figures illustrating the great reduction in the severity of the Indian outbreaks, coincidentally with a rise in the yearly vaccinations. As there had been no appreciable change in the sanitation of the Indian villages these data exposed the fallacy that the reduction in small-pox in the second half of last century was due to sanitary improvements and not to vaccination.

The only specific curative treatment in the dangerous toxic forms of bacillary dysentery was the antitoxic serum, which had to be made by injecting horses with increasing doses of the bacterial toxins, to which they soon became accustomed. After speaking of amoebic dysentery and liver abscess and its scientific treatment, he passed on to plague, and gave an account of the discovery of an efficient plague vaccine by Haffkine and its subsequent improvement. With regard to Malta or undulant fever, all the most important knowledge of this disease had been derived from animal experiments; for the causative organism was discovered in 1886, and was proved to be such by experiments on monkeys carried out by one of the greatest of British research workers, David Bruce. The same worker discovered the mode of infection to be the milk of perfectly healthy goats. Sir Leonard Rogers next retold the story of anti-typhoid inoculation in the Army during the great war, and of how the work might readily have been frustrated had the strenuous efforts of fanatics been successful. Apparently these fanatics had persuaded themselves that all the medical expert advisers of every army in Europe and America were wrong as regards the protective value of anti-typhoid inoculation, and that they, the prohibitionists, only were right, although presumably it was against their principles to have any scientific experimental investigations carried out, whereby alone such a complicated subject as the production of immunity in the animal system could be elucidated.

More specific curative remedies for widespread diseases had been discovered by animal experiments in about thirty years than had accrued from three thousand years of empiricism. Cinchona bark for malaria and ipecacuanha for amoebic dysentery appeared to be the only really curative remedies for serious specific diseases that had been discovered by empirical measures. Moreover, there was scarcely an important and commonly used drug in the *British Pharmacopoeia* the efficient employment of which did not depend on knowledge obtained by animal experiment. He instanced in this connexion the salvarsan group of drugs used in yaws and relapsing fever, the cure of sleeping sickness by Bayer 205 and tryparsamide, the antimony cure of kala-azar or black fever, and carbon tetrachloride in hookworm disease. Finally, he mentioned the two invaluable synthetic remedies, plasmoquine and atebrin, in the treatment of malaria. If the abolitionists had succeeded in their efforts fifty, or even thirty, years ago these potent new remedies would never have been discovered.

THE DEBT OF VETERINARY MEDICINE

Passing on to the benefits which animals themselves had derived through animal experiments, he mentioned first the instance of rinderpest or cattle plague, and the wonderful results which had followed the use of anti-rinderpest serum. Still better results were being obtained from protective inoculation against haemorrhagic septicaemia of cattle and against black quarter, another soil infection disease of young cattle. In the half-century that had elapsed since Pasteur's dramatic demonstration in sheep of the life-saving value of his protective vaccination against the invariably fatal effects of the inoculation of virulent anthrax bacilli, untold millions of animals had been saved from suffering and death by the use of his and later improved vaccines. He went on to mention swine erysipelas, braxy of sheep, joint-ill of foals, tetanus, swine fever, tropical ulcers, and many other conditions of animals in which immense relief had come about as the result of scientific experiment. The latest illustration of this was in connexion with the work done on distemper of dogs. It had been found that a healthy dog could be given lasting protection against distemper by the inoculation of a vaccine containing the killed distemper organisms, followed by inoculation of living virus a fortnight later. A survey undertaken in connexion with the recent *Field* investigation had shown that the incidence of distemper among 650 inoculated hounds belonging to twenty-three different hunting packs was only 1.4 per cent. and the death rate 0.3 per cent., whereas without inoculation the incidence among young foxhounds in this country was nearly 100 per cent., while the death rate was usually 50 per cent.

In conclusion, Sir Leonard Rogers said that literally millions of animals were being saved in civilized countries every year by the use of serums and vaccines discovered and made by means of animal experiments and in no other way. No scientist of standing would deny that some suffering was inflicted on animals in this work, but he maintained, with confidence, that the reduction of the sufferings of aimals as a class was many thousand times greater than any suffering inflicted on them in the discovery and preparation of these substances. Their opponents accused the scientists of cruelty. Surely the boot was on the other foot, for it was the prohibitionists, if they could have had their way, who would have added enormously to the sufferings of the animals which they held in such regard.

At the conclusion of the lecture a vote of thanks to Sir Leonard Rogers was moved by Sir THOMAS BARLOW and seconded by the Hon. Sir ARTHUR STANLEY.

The annual report presented to the business meeting of the society which followed drew attention to three outstanding reprehensible types of activity by the anti-vivisectionists: (1) active opposition and canvassing against the appeals for funds by hospitals and veterinary institutions; (2) propaganda implying that patients in the poor wards of hospitals were liable to be vivisected; and (3) canvassing consumers and friends to boycott manufacturing firms which scientifically tested their food or drug products before allowing them to be offered for sale to the public. In regard to the last-named activity, the committee trusted that no reputable firm would be intimidated by such actions, as the general public fully realized that the scientific standardization of drugs and food products was essential for the public good.

ST. GEORGE'S HOSPITAL

BICENTENARY COMMEMORATION

St. George's Hospital has just celebrated its bicentenary by a religious service at St. Paul's, Knightsbridge, and a reception at the hospital, besides which there is to be a festival dinner at the Mansion House on July 5th, from which it is hoped that the funds of the charity may substantially benefit. Since these celebrations were announced last March a leading article and a special article in the *Times* of June 13th have semi-officially informed the public that the hospital authorities are contemplating the sale of the site of the buildings at Hyde Park Corner and their re-erection in enlarged and more modern form on a more spacious site further from the centre of London. No more appropriate occasion could have been found for the writing of a short history of St. George's Hospital and its Medical School, and Dr. Joseph Blomfield has availed himself very acceptably of it in the commemorative volume published this week.[1]

FROM PETTY FRANCE TO HYDE PARK CORNER

Any history of St. George's, if it is to be adequate, must begin with the foundation of the Westminster Infirmary, the first general hospital in London to be supported by voluntary contributions, which was established in Petty France, Westminster, a street made famous by the one-time residence of John Milton and more recently familiar by the louring bulk of Queen Anne's Mansions. The infirmary was opened in the year 1720 under the name of the Westminster Public Infirmary. After two removals the governors of the charity, in 1733, found themselves in danger of having their house collapse, and other premises were sought for. Houses in James Street (now called Buckingham Gate) and in Castle Lane were offered, near where the Congregational Church and schools now stand, and this site was favoured by a majority of the governors. Westminster was at that time much more crowded than it is now and by a poor labouring class. The situation, moreover, was low and not far removed from the marshy ground around the Tyburn stream. These reasons moved an influential minority of the governors, including all the physicians and surgeons to the infirmary, to recommend removal from the slums to what was then the semi-rural suburb of Knightsbridge. Here, on higher ground at Hyde Park Corner, stood Lanesborough House, which was to be let at a rental of £60 per annum and which, in the opinion of the physicians and surgeons, was

"so near that the Governors might attend without inconvenience and yet far enough for the patients to have the benefit of a country air; which in the opinion of the physicians would be more effectual than physick in the cure of many distempers, especially such as mostly affect the poor, who live in close and confined places within these great cities."

This expression of opinion is surprising in that age of active treatment with drugs and counter-irritants. There followed a lively dispute carried on in a paper war. It ended in the majority establishing the infirmary at Castle Lane, which was afterwards to be removed to the present site of the Westminster Hospital in Broad Sanctuary, while the minority with substantial financial backing opened what was at first called "the Hospital near Hyde Park Corner."

Lanesborough House was a substantial three-storied red-brick building standing on the south side of Knightsbridge, at the corner of Grosvenor Gardens and subsequently just to the west of the Hyde Park Corner turnpike. In plan it may be represented as an upright H, with its central block and front door looking north across Knightsbridge to Hyde Park. After various alterations and additions this was the form it assumed, as may be seen in Horwood's plan of 1792, which was reproduced on a reduced scale in this *Journal*.[2] At length the old building became beyond repair, and Mr. Wilkins, the architect of the National Gallery, was commissioned to erect a new hospital. This he did at a cost of £40,000, and apparently without its becoming necessary to close the hospital at any time. This seems to have been achieved by changing the position of the entrance from the north to the east, so that access could be obtained behind the old building. The new building was complete in 1834, and still stands, although with many additions.

That the physicians were justified in claiming the benefits of country air for the new hospital may be concluded from a study of the maps of the period. Then, as now, Hyde Park and Kensington Gardens stretched uninterruptedly to the north-west; to the south and west there were fields and market gardens. To the east, as now, were the Green Park and the gardens of Buckingham House On the north side of Piccadilly building had not then extended beyond Clarges Street, where, until 1761, the turnpike-gate was situated. Although Grosvenor Square was built, most of Mayfair was open fields, with only occasional buildings. Beyond the boundaries of Hyde Park and Kensington Gardens, which are the same now as then, lay open country and villages such as Paddington and Kensington

The first general board of the founders of the hospital was held at the house of Mr. Carey, in Golden Square, on October 19th, 1733. Six physicians and three surgeons were elected medical officers, all of whom declared their "willingness to serve without fee or reward" These were the forerunners of a notable band of men, some of whom became world-famous. Space will not allow us to follow Dr. Blomfield in his interesting biographical sketch of them, but the names of Thomas Young, of John Hunter, who died in the hospital, of Brodie, Edward Jenner, and Baillie, must not escape mention.

THE MEDICAL SCHOOL

The physicians and surgeons established the Medical School in buildings in Kinnerton Street, Knightsbridge,

[1] *St. George's, 1733–1933.* By J. Blomfield, O.B.E., M.D. Copies can be obtained from the Medici Society, 7, Grafton Street, W.1, or St. George's Hospital, S.W.1. (Pp. 120; illustrated. 5s., or de luxe £2 2s.)

[2] *British Medical Journal*, 1929, i, 984.

rented from Sir Benjamin Brodie, including a lecture theatre and dissecting room, in the year 1836. These premises continued to be used until 1868, when new buildings were erected adjoining the hospital on land leased at a nominal rent by the Grosvenor Estate. These new buildings included a museum and library.

Before the establishment of this hospital school St. George's students were dependent for their scientific education on Lane's Grosvenor Place School, which continued to exist concurrently with it until it was closed in 1863.

In 1904 the then Prince of Wales (now King George V), appointed a committee to inquire into the financial relations between hospitals and medical schools in London. In accordance with the report of this committee St. George's gave up the teaching of anatomy and other allied sciences and became a clinical school. Relying on certain supposed assurances which were not carried into effect, the school at first suffered a great loss in numbers. It is now flourishing, and looks forward to a long career of usefulness, wherever the situation of the hospital may be.

HOSPITAL MIGRATIONS

If, and when, St. George's migrates from Hyde Park Corner, it will not be the first of the London medical schools or hospitals to do so. One of the most ancient, St. Thomas's, under the pressure of necessity, severed its long association with its neighbour, Guy's, and moved from Southwark to Lambeth more than sixty years ago. King's College Hospital, which is one of the younger hospitals, left the neighbourhood of the Strand, whence the slum dwellers of Clare Market and Drury Lane had disappeared, and removed a few years ago to Denmark Hill, whither its medical school is now following it. In neither case, we believe, has the removal been regretted by those most concerned.

It has been obvious to even the casual observer that St. George's has for years been occupying a valuable site which is too small for it, and it has seemed equally obvious that the site might be sold for a large sum and the proceeds devoted to the purchase of a larger yet less costly site near the middle of the area which the charity serves. But until lately it has not been found possible to put such a plan into practice. Now, however, the authorities have assured themselves that in the course of the next few years such a transaction will become possible. If so, another of the remaining landmarks of the neighbourhood of Hyde Park Corner will disappear.

HEALTH OF SCOTLAND

DEPARTMENT'S ANNUAL REPORT

The fourth annual report of the Department of Health for Scotland, dealing with the year 1932, has just been issued.[1]

Maternity and Child Welfare Services

The year 1932 showed the lowest birth rate recorded in Scotland, and a maternal mortality rate which, although higher than that for 1931, was lower than the average of the preceding five years. The infant mortality rate increased to 86 per 1,000 births as against 82 for 1931, and 85 for the average of the preceding five years. There were 579 deaths of women from diseases and accidents of pregnancy and childbirth, representing a rate of 6.4 per 1,000 registered births ; 246 of the deaths were attributed to puerperal sepsis. An inquiry has been undertaken into the circumstances attending births in Scotland over a period of six months from the middle of December, 1932, and it is hoped that this will throw some light on maternal mortality and morbidity. Deaths of children under 1 year numbered 7,841 ; the most important causes were congenital debility, premature birth, malformation, etc., in 43 per cent., bronchitis and pneumonia in 24 per cent., and diarrhoea, measles, and whooping-cough in considerably smaller numbers. Schemes for maternity and child welfare services are now in operation in all areas in Scotland except one, and the school health schemes have been continued by the reconstituted education authorities. With a view to securing a higher standard among midwives in Scotland a grant has been offered by the Department since 1927 to encourage trained nurses to undertake midwifery training, and the number of applications for this grant during 1932 was seventy-seven, making a total of 347 since 1927. The number of practising midwives in Scotland is estimated at 5,500, of whom 1,400 are in independent practice. Applications by midwives for medical assistance, which are on the increase, are made in approximately one out of every four confinements. The Department's regulations requiring notification of puerperal pyrexia in addition to puerperal fever have been effective in securing that cases of sepsis are brought earlier to the notice of medical officers of health, and arrangements have been made by most local authorities for consultant service, bacteriological examination, skilled nursing for home cases, and hospital treatment to be available for practitioners in these cases. The provisional figures for 1932 have shown a total of 1,206 notifications of puerperal fever and 1,081 of puerperal pyrexia. During the year 1,652 cases of ophthalmia neonatorum have been notified—as compared with 1,443 in 1931—of which 805 were notified in Glasgow. A clinical analysis of the 805 notifications, however, has shown that only 5 per cent. were of gonococcal origin. The number of schools inspected was 3,400, with a total of 831,792 children on the registers, of whom 247,272 in selected age groups were examined ; in addition, 128,021 referred by teachers or parents were examined, and 101,456 previously found defective were re-examined. The total number of examinations therefore dealt with 65 per cent. of the children. A distinct improvement in nutrition has been observed, despite the economic depression, and the percentage of children of " average or above average " nutrition has risen from 91.9 in 1923 to 94.5 in 1932, while the proportion of " below average " has diminished from 7.9 to 5.3 per cent., and of " very bad nutrition " from 0.3 to 0.2. Throughout Scotland generally there has been a gradual and consistent fall in the percentage of cases showing marked rickets. It is noted, however, that the medical officer of health for Glasgow reports that there are indications that rickets among pre-school children shows a tendency to increase, and the same fact has been noted in other industrial areas. Enlarged tonsils and adenoids have shown a definite increase over the past ten years ; some of this, however, is due to more frequent diagnosis and to the extension of facilities for treatment.

Infectious Diseases

There were increases in scarlet fever and pneumonia, and decreases in diphtheria and tuberculosis. The total number of all known cases of tuberculosis of various forms was 16,064, giving an incidence of 3.32 per 1,000 of the population. The total accommodation of beds reserved for tuberculosis is approximately 5,000, and the dispensaries and clinics now number forty-two. The number of centres for the treatment of venereal disease remains at fifty-two, as in the previous year. New patients to the number of 9,759 came forward, of whom 6,307, or 65 per cent., were found to be infected with venereal disease ; 284,372 attendances were made by infected persons for treatment. The report regards as a satisfactory feature of the work of these centres, indicating a growing confidence among the public to secure early and competent treatment, that an increasing number of patients who apply are found not to be suffering from venereal disease. On the other hand, the total number of defaulters who ceased to attend before being discharged as cured amounted to 53 per cent. ; this, however, was smaller than in previous years.

Hospital Services

Owing to considerations of economy there were few proposals for development of hospital facilities involving immediate expenditure, and only one scheme of

[1] Cmd. 4338. H.M. Stationery Office, 1933. (3s., postage extra.)

reorganization, that of Edinburgh, was formally approved by the Department during the year. This scheme removed from the category of Poor Law hospitals the institutions formerly known as Craigleith and Seafield Hospitals, and Pilton Infectious Diseases Hospital; these institutions have been converted to the purposes of general hospitals, and, to a certain extent, have been adapted for the instruction of students and the provision of facilities for clinical research. The Department has suggested the constitution of a Hospital Advisory Council for the south-eastern region of Scotland to the favourable consideration of the Town Council of Edinburgh.

Highlands and Islands Medical Service Fund

At the end of the year the doctors under agreement to render service under this scheme numbered 153. Surgical services, based on the voluntary hospitals at Stornoway, Kirkwall, and Lerwick, continue to demonstrate that they are indispensable to the communities they serve, and the grants are being continued, though at a somewhat reduced rate. Surgical services have also been inaugurated in Caithness, in the Lochaber district, in Sutherland, and in South Uist. Assistance has been granted by county councils in Inverness and Zetland for the provision of houses for doctors, and on the island of Eriskay for a district nurse. The expenditure, including the grant-in-aid of £70,000 and £10,000 transferred from the Scottish national health insurance in respect of mileage, amounted to £81,870.

National Health Insurance

Important developments of the national health insurance scheme were made by the National Health Insurance and Contributory Pensions Act, 1932, which for the most part came into effect on January 1st, 1933. The principal changes made by the Act relate to the rates of sickness benefit for women, the extent of free insurance to contributors who have ceased to pay contributions owing to cessation of employment, and arrangements in regard to arrears of contributions. The rates of disablement and sickness benefits were reduced, but it was pointed out by the Government actuary that the new rates would only be able to support the benefits if the claims were maintained at a level at least 10 per cent. lower than the average claims for 1928–30. As a result of the passing of the 1932 Act, an unemployed person who at the time of his becoming unemployed had acquired a fairly substantial standing in insurance, will be retained in full insurance for a period of from two and a half to three years if he is unable to continue insurance payments owing to inability to obtain work. This will carry on free insurance up to not later than December 31st, 1935. The membership of approved societies under the insurance scheme amounted to 1,195,000 men and 630,000 women, a total of 1,825,000 insured persons. An upward movement in the rate of expenditure on cash benefits during 1932 is recorded, the total for sickness and disablement benefits during 1932 having been £1,786,000 as compared with £1,664,000 in 1931. The excess was mainly among the insured men, and from the Department's investigations appears to have been due largely to the severe epidemic of influenza which ran its course towards the end of the year. Examinations of insured persons by the Regional Medical Service showed that the great bulk of cases referred were submitted by approved societies; the falling off in the number of references submitted by practitioners, however, has continued. The total number of cases referred was 62,294; in 26,019 of these the practitioner's certification was upheld, and in 11,987 it was reversed. The charge on approved societies for medical benefit was maintained during 1932 at the same rate as in recent years—namely, 12s. 1d. per person—and from the fund so provided there was made payable to insurance practitioners £863,550 in capitation payments, £52,500 in payment for mileage, and £10,000 in respect of medicines and appliances provided by dispensing doctors. The payments to chemists and doctors in respect of medicines included sums totalling £9,200 for insulin. The report judges that the medical service given by insurance practitioners may be regarded as of a satisfactory standard from the fact that during the year under review only thirty-two cases of alleged failure on the part of practitioners to carry out their obligations were reported. Twelve of these were dismissed, and in nineteen penalties were inflicted aggregating £159 8s. In one case only was the practitioner's name removed from the list in consequence of breaches of his term of service.

[To be concluded]

THE UNIVERSITY OF LONDON

FOUNDATION STONE OF BLOOMSBURY BUILDINGS LAID BY THE KING

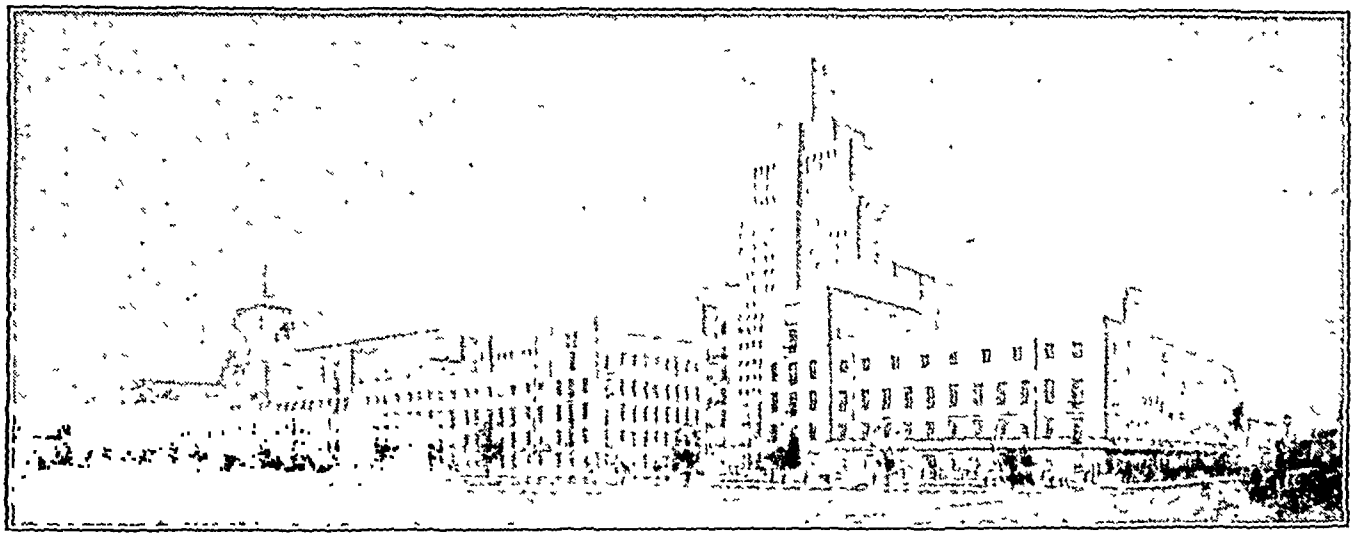
On Monday last, June 26th, with appropriate ceremonial, the foundation stone of the new home for the University of London in Bloomsbury was laid by the King. The Queen was also present, and a great assembly, principally representative of British, Imperial, and foreign universities and learned societies, gathered in honour of the occasion. The ceremony took place at the south-western corner of the new site, opposite the northern façade of the British Museum. Here a dais was erected confronting a gigantic semicircular marquee accommodating three thousand guests and students, and the academic gowns everywhere worn made it a brilliant spectacle. The principal procession to the dais to await the King and Queen was formed at the London School of Hygiene and Tropical Medicine, which is adjacent to the site. It was led by the official staff of the University, the standing committee of Convocation, the Senate, and the Court. It included four former Vice-Chancellors (Sir Holburt Waring, P.R.C.S., Professor E. A. Gardner, Sir William Beveridge, and Dr. J. Scott Lidgett), and the Chancellors of many sister universities, among them those of Dublin (Lord Iveagh), Aberdeen (Lord Meston), Glasgow (Sir Donald MacAlister), Leeds (Duke of Devonshire), Birmingham (Lord Cecil of Chelwood), Victoria University of Manchester (Lord Crawford and Balcarres), Durham and Queen's University, Belfast (Lord Londonderry), Cambridge and St. Andrews (Mr. Baldwin), and the Vice-Chancellor of Oxford (Rev. F. J. Lys). After these came the Chairman of the London County Council, the Lord Mayor of London, the Mayor of Holborn, the Public Orator (Professor Harold Butler), the Principal of the University (Dr. Edwin Deller), Sir E. Graham-Little, M.P., the Chairman of the Court (Lord Macmillan), the Chairman of Convocation (Mr. S. L. Loney), the Vice-Chancellor (Professor L. N. G. Filon), and the Archbishop of Canterbury. The Chancellor of the University, the Earl of Athlone, brought up the rear. In all, nearly 150 universities and academies joined in the celebration, and the colours of the East were very noticeable.

Their Majesties, who were accompanied by Lord Irwin, the Minister for Education, were received by the Chancellor of the University and the Mayor of Holborn, and after certain presentations had been made the Chancellor in an address to the King spoke of the abiding faith which those to whom the affairs of the University were entrusted felt in her great future. The University, he said, had never lacked friends, and, with great and honoured exceptions, those friends had been mainly members of her own family; yet she had never possessed a home of her own, suited to her special needs, and worthy both in spirit and in form of the great city whose name she bore.

"The ceremony which your Majesty has graciously consented to perform this afternoon marks the commencement of a new era, for the University of London is standing upon the threshold of the great inheritance she has built up for herself, a heritage which means nothing less than that she shall become not only the University of London in name but in deed and in reality London's University. That London and the City of London are awake to this fact is evidenced by the enthusiasm with which they have welcomed the idea of a central home for their University and by the most generous manner in which they are helping to further that

end. The splendid buildings which will arise here in the heart of London above and around the stone which your Majesty is about to lay will be the living embodiment of that idea. . . . We may not all be here to see the completion of those buildings, but we are well content that what is being done to-day marks the beginning of one of the greatest periods in the history of the University of London."

THE KING'S SPEECH



The King, after expressing his pleasure at being present, and thanking the Chancellor for his loyal address, said that the University "has waited long for a home that she could truly call her own, and we all now rejoice to see the beginning of a finely planned group of buildings which will serve as headquarters for her far-reaching work and influence. I count it of good omen that in these difficult times we have the opportunity of showing an unshaken faith in the inestimable benefits of knowledge and education. No less auspicious is the alliance in this good cause between friends of education in the Old World and the New. The Rockefeller Foundation, our own Government, the citizens of London in corporate and in private capacities, all share in a memorable achievement." After a welcome to the representatives of Dominion and foreign universities, his Majesty concluded: "Bloomsbury has long been a centre of learning, and it is appropriate that we should inaugurate here, on this great site, a stately plan of buildings worthy of London and of her University. I hope that this noble enterprise, which has begun so well, may attain an early and triumphant completion."

After prayers by the Archbishop of Canterbury, the King duly laid the foundation stone, first depositing in a cavity under it a casket containing the University Calendar, the Order of Proceedings, a copy of a brochure issued for the occasion, a newspaper of the day, and certain current coins. The trowel was handed to him by the architect, Mr. Charles Holden, and a silver mallet and spirit level by the Vice-Chancellor. His declaration that the stone was "well and truly laid" was followed by a fanfare of trumpets. Before their Majesties left, a number of further presentations were made, and they signed the visitor's book, and accepted specially bound copies of a descriptive account of the new buildings.

THE BLOOMSBURY SITE

The scheme thus inaugurated, whereby a new centre of University life in London is established, and some 10½ acres of Bloomsbury will be entirely rebuilt, has already been outlined in these columns. As the Earl of Athlone stated in his address to the King, although the University will in a few years' time celebrate its centenary, its first charter having been granted at the end of the reign of William IV, up to now it has had no worthy centre or focus. In 1927 the Rockefeller Foundation made a magnificent offer of £400,000 towards the purchase of a site on which adequate headquarters for the University might be built. The site in Bloomsbury was acquired for £525,000. It is bounded on the south by Montague Place, on the east by Russell and Woburn Squares, on the north by Gordon Square and Byng Place, and on the west by Malet Street, which, from being a commonplace thoroughfare, bids fair to become in a few years' time one of the great streets of the capital. Although the students of the University are scattered over a large number of schools and institutes, the greater number attend colleges situated within a radius of one mile, and University College itself is at the northern extremity of the site.

The work of development will be carried out in stages spread over many years. The vertebrate type of planning has been adopted for the whole area, so that the composition will be impressive even while incomplete. Excessive height on all frontages has been avoided, and the adjacent houses will not be overlooked. The exterior of the buildings will be faced to a height of about 15 feet with granite, and above with Portland stone; the core of the main structure will be of brick. A series of quadrangles will be laid out as gardens, with grass lawns. The first building to be erected will be the senate house and official headquarters; adjoining this will be the University hall, where ceremonials will be staged. The library, where for the first time the literary and other treasures of the University can be displayed to advantage, will probably be placed above the senate house and will occupy part of the tower, which, 200 feet in height, will dominate the whole group.

ARCHITECT'S PERSPECTIVE DRAWING OF THE NEW BUILDINGS IN BLOOMSBURY FOR THE UNIVERSITY OF LONDON.

There is an idea in some quarters that all the colleges and institutions of the University will be transferred to this site. Such a plan would be quite impossible; the sites of some of the colleges are themselves as large as the University site. Moreover, such a concentration, even were it feasible, would not be advantageous, for the needs of the vast number of students who live in all quarters of London at home or in lodgings or hostels have to be considered. Again, the medical schools must, of course, continue to be attached to the great London hospitals. But from the very fact that some of its constituent elements must be considerable distances apart, the establishment of a worthy centre of the University becomes all the more important.

The returns from universities and university colleges in receipt of Treasury grants for the academic year 1931–2 has just been issued by the University Grants Committee (H.M. Stationery Office, 1s. 3d.). Of the 48,510 full-time students to which this publication relates, medicine and dentistry claims 10,379; of these 9,107 were men and 1,272 women. The schedule of degrees and diplomas obtained during the year and analysed according to faculties gives a total of 960 degrees and 1,176 diplomas under "medicine including dentistry" in Great Britain.

OXYGEN THERAPY

As a general rule useful additions to our therapeutic knowledge are taken up quickly by the profession, but it is open to doubt whether oxygen is employed as much as it should be. During the war continuous administration of oxygen was widely practised in the treatment of pulmonary oedema from poison gases. The experience then obtained of the great value of oxygen in cases of gas poisoning encouraged its use in civil practice, and its importance as a therapeutic agent became more widely recognized during the ten years between the close of the war and the discussion held in the Section of Therapeutics and Pharmacology at the Annual Meeting of the British Medical Association in Edinburgh. Since 1918 there have been published a large number of clinical and experimental studies, recently summarized by Boothby.[1] The theoretical basis of arterial anoxaemia and its effects on the body have been expounded by Haldane and other workers,[2] and the indications for the use of oxygen in disease, with the evidence of its beneficial action, have been laid down by Stadie,[3] Meakins and Davies,[4] and many other English and American observers. It has been shown that anoxaemia is insidious in its onset and can exist without cyanosis. Indeed, when cyanosis first appears in the anoxaemia of lung disease the arterial blood is already seriously lacking in oxygen. Anoxaemia must be treated early, for if it goes on too long irreparable damage may be done to the respiratory centre and other parts of the central nervous system, on which falls the brunt of oxygen shortage. The causes of insufficient oxygenation of blood in the lungs may be put briefly under two headings: first, when enough oxygen fails to reach the alveoli; and, secondly, when there is interference with the passage of the gas to the blood. Inadequate ventilation may be either local, as in areas of collapse, or general, as in shallow breathing. Pulmonary oedema or other alveolar exudate is considered to cause delay in the passage of oxygen, so that venous blood passes through the pulmonary capillaries without receiving enough oxygen to saturate it. This makes a sort of venous short circuit. In pneumonia both these factors may be operative. This disease and pulmonary oedema constitute the commonest indications for oxygen therapy. They occur frequently after major surgical operations, and it is in this group of cases that oxygen is of greatest value, because the virulence of the infecting organisms is commonly less than in cases occurring spontaneously in healthy people: the anoxaemia, therefore, assumes a greater relative importance. In lobar pneumonia there are so many complex factors influencing the mortality that the exact part played by oxygen is difficult to assess; the effect of anoxaemia is mingled with that of the toxaemia.[5] In these circumstances an immediate and dramatic result of oxygen therapy is seen only occasionally: however, it needs but a few trials to convince any unprejudiced observer of the beneficial effect on the circulation and on the nervous system.

Why is it, then, that oxygen is not more widely used in practice? It may be that the significance of acute cyanosis is not generally recognized because chronic cyanosis is common and harmless in conditions such as emphysema and congenital heart disease, in which a compensatory increase of haemoglobin occurs. There can be little doubt that the extra attention needed for continuous oxygen administration, combined with the difficulty of obtaining the oxygen and other necessaries, is in some instances enough to prevent its use. Perhaps it is not sufficiently recognized that the good obtained from oxygen is not proportional to the amount given. The oxygen chamber or tent is by far the most agreeable and effective method, but this for the present is employed only in institutions, at least in this country. What complicates this method is the necessity for keeping the carbon dioxide at a proper level and also for regulating the temperature. The administration of carbon dioxide as well as of oxygen is very beneficial in carbon monoxide poisoning, but has not yet been proved to be of value in the majority of cases of pneumonia.

The simplest and cheapest way of giving oxygen is by the nasal catheter; this has been shown to have a definite effect on the oxygen content of the arterial blood, even when quite small quantities of oxygen are given.[6] At its simplest it consists merely of a fine rubber tube inserted three inches into the nostril, held to the cheek by plaster and connected to an oxygen cylinder. A reducing valve is desirable; and other refinements include a blunt-ended rubber tube with a hole lateral instead of terminal and smeared with cocaine ointment. To warm the gas and also to provide a visible flow, it can be passed through warm water. A glass jam jar capped with strong sheet rubber, pierced to receive two pieces of glass tubing, will outlast an expensive Woulfe's bottle. The flow of oxygen should be as fast as can be comfortably borne. Once the oxygen is flowing no attention is needed beyond a cautious turn of the valve to maintain the flow and the occasional detachment of the tube from the water flask to allow of the removal of condensed moisture. The catheter may be left in position for days. The cost of the oxygen, given continuously from small cylinders—the most expensive way—need not be more than 10s. a day.

SCARLET FEVER IN ENGLAND AND WALES

Miss Hilda M. Woods of the London School of Hygiene and Tropical Medicine has recently made a detailed statistical study of scarlet fever in England and Wales since 1900, under the headings of the trend of mortality and possible factors influencing this trend, changes in the age and sex distribution of mortality, morbidity, seasonal incidence, and case fatality. As the Medical Research Council points out in the preface to her report,[1] Miss Woods has had an advantage over statisticians of an earlier generation in that she has been able to study not only mortality but prevalence. In striking contrast with what happened in the second half of the last century the deaths from scarlet fever in England and Wales have shown such a remarkable diminution, due to lessened severity of the disease since 1900, as to suggest that the lowest death rate has been reached. The past history of the disease, however, should serve as a warning against excessive optimism in this respect, for variation in intensity from extreme gravity in the last years of the eighteenth century to a mild type of the beginning of the nineteenth century was followed by a severe type in the 'fifties. A study of the mortality figures for London, Liverpool, Manchester, and Birmingham reveals that the change in the trend of mortality from scarlet fever has not been uniform, but has shown more or less wide variations. In the pre-war period, for example, the greatest improvement in mortality occurred in Liverpool, whereas since the war the greatest decline has occurred in Birmingham. Contrary to what was first maintained by sanitary authorities Miss Woods found no evidence that hospital isolation has been effective in reducing the prevalence or mortality of scarlet fever. This conclusion bears out that of the Committee of Medical Officers of the Ministry of Health,[2] who reported in 1927 that "the incidence of the disease in the country generally appears to show no marked reduction as the result of hospital isolation, or indeed of any other measure of public control."

As regards the possible factors influencing the spread of scarlet fever, the prevalence of vermin, poor social conditions, and low rainfall have among others been incriminated. While it is true that in London scarlet fever was more prevalent in the poorer and overcrowded areas, in Birmingham the greatest incidence was among the better-class artisan dwellers, and in Glasgow the attack rate declined as crowding increased. In London a definite relation was shown by Longstaff in 1880 and Brownlee in 1923 to exist between wet years and low prevalence of scarlet fever, but this association did not exist in Liverpool, Manchester, or Birmingham. As regards age distribution it was found that while the absolute mortality for scarlet fever had fallen at every age, the relative mortality in the later years of life had increased. A similar shifting of the mortality in scarlet fever from the lower to the higher ages was found by Pope in Providence, U.S.A., in 1926. Although the mortality of scarlet fever has declined much in the course of the last thirty years, there is no evidence that its prevalence has diminished to any extent, the attack rate in 1911 being 2.9 per thousand and 2.76 in 1930. A study of the geographical distribution of the disease shows a high incidence in London and Essex, while in Middlesex, Bedfordshire, Wiltshire, and Denbigh the attack rates exceed 2,500 per million population. On the other hand, after the epidemics of 1920–1, there has been a marked fall in the attack rate in Wales, where in 1930 it was 2.87 as compared with 4.35 per 1,000 in 1920. In London (1930–1) and in Manchester (1896–1929) the maximum attack rate was at the age of 5 years—the age of compulsory school attendance. A study of the fatality rates at the Eastern Hospital from 1895 to 1914 showed that the greatest risk of death occurred during the first twelve months of life, though the chance of an attack was least among infants.

While the possibility of a reversion to a more dangerous type of scarlet fever in this country cannot be excluded, there seem to be ample reasons for believing that at least no sudden change is at all likely to occur. "Practical experience and statistical analysis appear to point to the same conclusion—namely, that the problem of scarlet fever *now* is an *essentially* different one from that of even a generation ago."

CLINICAL SIGNIFICANCE OF RETICULOCYTES

In a recent paper Tsonos[1] estimates the content of reticulocytes in normal blood as up to 5 per 1,000 red cells (25,000 per c.mm.). In most anaemias, infections, and intoxications these cells increase in number, whilst in cachectic conditions—severe chlorosis and aplastic anaemia—they occur in small numbers only or are entirely absent. Iron and arsenic medication may lead to a considerable reticulocytic reaction. The usual view taken is that the appearance of these cells in the circulation is an index of the increased function of the bone marrow, and, as such, important in the prognosis of anaemias. The author, struck by the fact that children and infants of the same age varied in their tendency to anaemia associated with infections or nutritional factors, sought to correlate this with the reticulocytic response, using brilliant cresyl-blue in the moist chamber. In eleven cases of so-called constitutional anaemia of infants without infection or nutritional disorders in which the haemoglobin content was between 50 and 60 per cent., and the red cell count between 3 and 4½ millions, he found five cases with reticulocytes up to 8 per 1,000, four up to 9 per 1,000, and two up to between 10 and 19 per 1,000. These differences could not be correlated with the clinical condition or the haemoglobin content. Treatment with iron, copper, arsenic, and, on two occasions, liver, led in ten cases to marked improvement in the blood picture, but in three cases only was there an initial rise in reticulocytes, which later regressed, and all of these cases had originally a count higher than normal: those with original

[1] *Klin. Woch.*, April 8th, 1933.

normal reticulocyte count remained unchanged, as did also a therapeutically intractable case. Examination of fifteen children, aged from 2 months to 12 years, with various infections but no anaemia, showed only three cases of increased reticulocytosis, these all being severely ill. In fifteen cases of infection with mild anaemia five showed " high-normal " values and six values between 10 and 19 reticulocytes per 1,000 R.B.C. ; and in seventeen cases with severe anaemia five were " high-normal," three between 10 and 19 per 1,000, and three between 20 and 30 per 1,000. Thus again no constant relation between degree of anaemia or severity of infection could be demonstrated. During convalescence seven children with 10 to 20 reticulocytes per 1,000 R.B.C. showed a gradual return to a normal count. Treatment with metals or liver, either in the later stages of the infection or during delayed convalescence, showed in five mild cases with a reticulocyte count between 5 and 18 per 1,000 a return to normal count without any initial rise in reticulocytes. Of seven severe cases which were followed for a considerable time there was in four cases a rise in reticulocytes up to 30 per 1,000 and in one case up to 60 per 1,000, these high values returning to normal slowly. These observations are interpreted by the author as showing that reticulocytic formation is a constitutional reaction more easily evoked in some individuals than others, and that there is a certain but not constant relation between the severity of the anaemia and the reticulocyte reaction. Very real importance is attached to the observation that improvement may occur with or without an initial rise in reticulocytes. In further support of this he cites two cases of mild and two of more severe anaemia in which recovery took place after iron medication without any change in the reticulocyte count and four severe and two mild cases in which, in spite of very marked reticulocytosis, recovery did not occur. A theory of the significance of reticulocytes in the blood is put forward which does not attribute their increase to stimulation of blood regeneration, but rather to stimuli which, acting on the bone marrow, disturb the normal inhibition of their too rapid release. Thus the author considers that causes which lead to anaemia may also lead to increased blood reticulocytes by acting in the above way. Reticulocytic reaction to certain drugs, it is suggested, may be due not to regeneration, but to toxic action on an already unstable mechanism.

THE CONDITION OF THE PROFESSION

The whole medical profession, in the English-speaking world at least, always listens with respect and admiration to anything Dr. Harvey Cushing has to say. He has written an article entitled " Medicine at the Cross-roads," which appeared in the *Journal of the American Medical Association* for May 20th last. In it he contemplates the medical profession as a patient who is supposed to be seriously ill and is menaced by a multitude of advisers. In a pleasantly cynical manner he attempts to adjudicate between, or to reconcile, a variety of diagnoses, and more than suggests that a period of quietude, even though it involves some endurance of accustomed ills, is more desirable than any application of drastic remedies, either self-administered or state-imposed. Such an opinion, coming from such a quarter, deserves, and will no doubt receive, careful consideration, both from the patient and from the rest of the consulting physicians and surgeons concerned with the case. It is scarcely to be supposed, however, that any of the parties involved will lightly acquiesce in a policy of masterly inactivity. It is probable that at least some minor adjustments of training and of environment will be adjudged to be necessary. Dr. Cushing's article is a delight to read, though perhaps a little long-drawn-out. Some few among its many wise dicta relating to questions of the day may be quoted here:

" Pressure is being brought to bear to have all bedside teaching permeated with emphasis laid on prevention, as though this were something novel. It would be a slur on the student's intelligence for a surgeon, let us say, to point out . . . that he wears rubber gloves to ' prevent ' infecting the patient, gives the anaesthetic to ' prevent ' pain, removes the appendix to ' prevent ' peritonitis, and so on *ad infinitum*."

" In actual fact, our schools no longer pretend that the degree of M.D. which students attain after four years prepares them for practice ; we merely bring them to the point at which they must on their own initiative scramble for a hospital appointment where they hope to acquire what the school has neglected to give them—the training necessary to secure a licence to practice."

" There has been much lamentation about the disappearance of the family doctor, but . . . he's not often heard from, and I am far from believing he's a vanishing species, in spite of our scholastic neglect of him in a system which, by over-emphasis on research and prevention, rather than on diagnosis and treatment, gives him while an undergraduate a sense of inferiority."

" What this puzzled world needs perhaps is more study of the past, fewer commissions and surveys of the present, and a greater number of philosophically minded, self-supporting, and law-abiding persons who can see all round their particular problem and independently devote themselves to it as do most doctors."

Yet though these passages contain important correctives to several current judgements, they are but random samples from a provocative presentation of medicine to-day as a clinical problem, which should be read in its entirety.

MEDICAL RESEARCH IN CALCUTTA

The annual report of the Calcutta School of Tropical Medicine[1] for 1932 is remarkable for the amount, the variety, and the quality of the research work reported. It is published in three volumes, one of which contains the annual reports of the directors and professors in charge of various departments, while the other two contain reprints of fifty-six published papers, and it is mentioned that fourteen additional papers were published from the school during the year. This large output is explained by the fact that the school is making an earnest attempt to grapple with the bewildering variety of diseases that afflict the Indian sub-continent. The director, Lieut.-Colonel H. W. Acton, mentions first the gratifying fact that at last the problem of the transmission of kala-azar has been solved, and that the disease has been proved to be transmitted by the sandfly *Phlebotomus argentipes*. A systematic examination has been made of a series of organic pentavalent antimony compounds in relation to their efficacy in the treatment of kala-azar, and of these stibosan has

[1] Calcutta: Bengal Government Press. 1933. (Gratis.)

been found to be the most effective. Several papers deal with the action of plasmoquine and atebrin in malaria, and the results recorded indicate the great importance of these compounds. The economic value of intelligent research is illustrated by the following facts mentioned in the director's report. A total dosage of 0.32 gram of plasmoquine had been recommended for the sterilization of gametocytes, but controlled investigation showed that 0.04 gram was equally effective. This change in dosage saved about £5,000 in a large-scale investigation of the action of plasmoquine in malaria. Hexyl-resorcinol was found to be unsuitable for the treatment of ankylostomiasis, because in comparison with other remedies it was relatively expensive and ineffective. Lieut.-Colonel Chopra, continuing his investigations on drug addiction in India, has found that during the last decade chloral hydrate has become widely used in the Punjab, apparently as a cheap substitute for alcohol in producing stupor. The points mentioned above are only a sample of the large mass of pharmacological, pathological, and bacteriological work that was produced during last year by the Calcutta School of Tropical Medicine. The director and his associates are to be congratulated on the manner in which they are advancing knowledge about the prevention and treatment of tropical diseases.

THE NATIONAL PHYSICAL LABORATORY

The yearly chronicle of work done at the National Physical Laboratory[1] covers a vast and various field. Metallurgy, aerodynamics, electrotechnics, and general physics in innumerable ramifications all come within its province. Only at a few points does it touch on medicine. The work upon the precise measurement of *x*-ray dosage and on the perfecting of protective measures is being continued. Radium to the total quantity of nearly 6½ grams was submitted to the laboratory for testing during 1932, and several hundreds of containers have been tested for leakage and repaired. At the request of the King's Fund twenty tubes belonging to the four-gram bomb were examined prior to being reissued in units of one gram to each of four London hospitals. The mounting of the one-gram units was also carried out at the laboratory. The laboratory undertakes the general arrangements for the storage and distribution of national radium, and consignments of radium have been distributed during the year to national radium centres and to three of the new regional centres. Certain of the national radium containers which were originally tested over two years ago have been retested during the past year in order to discover whether the radium supplied is free from mesothorium and its disintegration products. A number of radium containers have been inadvertently damaged by fire during the year, and the laboratory has been able to render effective assistance on occasion in recovering containers from hospital incinerators. At the request of the Otological Section of the Royal Society of Medicine, the laboratory has been carrying out experiments on the rates of decay of tuning-forks such as are used in otological testing. A simple instrumental test was devised in conditions which simulated those commonly adopted by otologists in tests of deafness, the rate of decay of a fork held in the hand being determined both in free air and with the base of the fork pressed against an artificial substitute for the mastoid bone of the skull. Attention was paid to the type of finger-grip employed, and to the effect of lack of balance of the prongs on the rate of decay. This latter condition not only gives rise to a more rapid decay than when the fork is in balance, but appears to accentuate the usual tendency of forks to decay at a greater rate when the amplitude is large than when it is small. Another piece of work has been undertaken at the request of the Dental Disease Committee of the Medical Research Council—namely, the *x*-ray study of tooth structure, in particular the difference between tooth enamel and dentine as revealed by *x* rays. The crystalline constituents of both these substances are nearly identical, but the arrangement of the crystallites differs greatly. In dentine the crystals are oriented at random, whereas in enamel there is a markedly preferred orientation, the nature of which has been determined. There is also a pronounced difference between enamel and dentine in their absorbing power for *x* rays, dentine being much more transparent. This throws some light on the amount of material other than crystalline in the different parts of the tooth. The enamel contains a higher percentage of crystalline material. Arrangements have been made for a continuation of the work, which has been extended to the study of enamel decay, and certain differences already found between normal enamel and enamel subject to decay are being further investigated. The annual inspection of the Laboratory by members of the general board took place on Tuesday of this week. Visitors were received by Sir F. Gowland Hopkins, President of the Royal Society, chairman of the board, Lord Rayleigh, chairman of the executive committee, and Sir Joseph Petavel, the director.

[1] Report for the Year 1932. H.M. Stationery Office. (14s. net.)

ANIMAL PATIENTS

Dogs fitted with prosthetic appliances are not uncommon in these days when the streets take their toll of dogs as well as of human beings, but it is unusual to hear of a dog with an artificial eye, or with a denture, including gold bridge work. Sir Frederick Hobday, who delivered the eighth Macalister memorial lecture at the National Temperance Hospital on June 22nd, described these and many other curious examples of veterinary surgery and orthopaedics. The use of *x* rays is now general in veterinary practice, chiefly for the detection of foreign bodies which have been swallowed. Sir Frederick Hobday rather suggested that dogs specialize in the things they swallow. One animal, for example, has a fancy for screws, a small collection of which has been removed from its stomach. Other dogs regard their interior as a money-box, and about sixpence in coppers, which should have been the property of the confectioner to whom the dog was sent to buy buns, was discovered in one canine stomach. A dog was recently brought to the Royal Veterinary College having swallowed a diamond stud of the value of fifteen guineas; the stud was retrieved. Among horses there were formerly many cases of swallowed foreign bodies, but this is now rare, owing to the practice among careful owners of going over the corn-feed with a magnet for the removal of small pieces of metal. Sir Frederick Hobday reminded his audience of the large amount of professional preparation which nowadays goes to the making of a veterinary surgeon. The student must

matriculate before beginning professional studies, following which a minimum period of five years is spent before the diploma of the Royal College of Veterinary Surgeons is granted; even so, a large proportion of students extend their studies for a further six months to take a university degree. After qualification the diplomate may specialize in public health, in which case he spends a further year in obtaining a post-graduate diploma, or he may decide to enter for tropical veterinary medicine, or to specialize as a consultant in a particular field, all of which entails further preparation. The veterinary course is open to women and men alike, and at present there are twenty-nine qualified women veterinary surgeons, and a good many women students in the different colleges. The Royal Veterinary College has at the moment nearly seventy women students, some of whom have already done brilliantly in examinations. The prospects of the veterinary profession for women appear to be good. Women seem capable in an unusual degree of inspiring confidence in animals, and of converting their animal patients into friends. The girl seeking a career, if she had brains and loved animals, might be well advised, said Sir Frederick Hobday, to qualify in a veterinary course, and afterwards specialize in canine medicine.

THE 1,500th SUPPLEMENT

Our *Supplement* of this week is the fifteen hundredth ordinary number. The propriety of issuing a supplement had been under consideration for some time before the first number appeared on February 5th, 1903. In October, 1901, the Council adopted a recommendation to the effect that in view of the amount of official matter which had to be published in the *British Medical Journal* it was desirable to issue from time to time supplements containing such material. The recommendation was not immediately acted upon, because it was a time of transition, and it seemed well to wait until the new constitution was in full working order. At first the *Supplement* was issued at irregular intervals as matter accumulated, but since the beginning of 1905 it has appeared, with very few exceptions, every week. It varies in size according to the exigencies of the moment; on several occasions it has contained sixty-four pages, either when the Annual Report of Council was published or when there has been a special Representative Meeting. In addition, special issues have occasionally been published, such as the *Canadian Supplement* in connexion with the Winnipeg Annual Meeting in August, 1930, the *Colonial Medical Services Supplement* in July, 1931, and the Register of Bio-Physical Assistants on several occasions. In 1912, at the height of the Insurance Act upheaval, the two volumes contained 1,484 pages. During the war the bulk was very much diminished, but it gradually grew again as the activities of the Association expanded in many directions, though the number of pages has never approached that of twenty years ago. The object with which the *Supplement* was established was that members should be able to follow every phase of the British Medical Association's work, and to appreciate its variety and extent. In this way it was believed that a larger proportion of members would be stimulated to interest themselves in the Association's efforts for the furtherance of reforms within, as well as without, the profession.

COMMITTEE ON SCOTTISH HEALTH SERVICES

The Secretary of State for Scotland has appointed a Committee "to review the existing health services of Scotland in the light of modern conditions and knowledge and to make recommendations on any changes in policy and organization that may be considered necessary for the promotion of efficiency and economy." The members of the committee are: Sir John Dove-Wilson, K.C., ex-President of Supreme Court of Natal (chairman), Mr. George Bonar, Dr. James L. Brownlie, Mr. Ian Carmichael, Professor E. P. Cathcart, M.D., F.R.S., Dr. Robert W. Craig, Provost David Fisher, Professor Alexander Gray, Sir Andrew Grierson, Dr. John Jardine, Dr. Alexander S. M. Macgregor, Lady (Leslie) Mackenzie, Mr. W. M. Marshall, Dr. Alexander Miles, Bailie Violet Roberton, Mr. J. M. Vallance, Mrs. A. M. Chalmers Watson, M.D., and Mr. Joseph Westwood. The secretary of the committee is Mr. Niven F. McNicoll of the Department of Health for Scotland, 121a, Princes Street, Edinburgh, to whom all communications should be addressed.

On March 18th we announced that arrangements had been completed, after nearly three years of consideration and postponement, for the establishment of the British Post-Graduate Medical School at Hammersmith. Work on the building has now been begun, and the foundation stone will be laid by Mr. Neville Chamberlain, Chancellor of the Exchequer, on July 17th.

The new buildings of King's College Hospital Medical School at Denmark Hill will be opened by H.R.H. Prince George on Tuesday, July 4th, at 3 p.m., when Admiral of the Fleet Earl Beatty, chairman of the committee of management, will preside.

The Buckston Browne Surgical Research Farm at Downe, Kent, will be formally opened by Sir Holburt Waring, President of the Royal College of Surgeons of England, on Wednesday, July 12th, at 5 p.m.

ORDER OF ST. JOHN OF JERUSALEM

The King has approved promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem, as follows:

Knight of Justice.—Lord Dawson of Penn, G.C.V.O., K.C.B., K.C.M.G., M.D., P.R.C.P.

Knight of Grace.—Major-General J. T. Fotheringham, C.M.G., M.D. (Toronto), Colonel Sir Edward N. Thornton, K.B.E., M.R.C.S. (Pretoria).

Commander.—Lieut.-Colonel W. K. Clayton, C.M.G., M.D., H. W. Horan, M.B., S. McCormac, M.B., H. A. Beatty, M.D., Colonel L. Drum, C.B.E., M.D., Major-General Sir John W. D. Megaw, K.C.I.E., M.B., I.M.S., A. Dobson, M.R.C.S.

Officer.—J. Cairns, O.B.E., M.B., C. Armstrong, M.B., Major J. H. Dixon, M.D., Brevet Colonel J. Wallace, O.B.E., M.D., E. A. Braithwaite, M.D., Lieut.-Colonel O. A. Cannon, M.B., Colonel J. T. Clarke, C.B.E., M.C., M.D., Lieut.-Colonel G. G. Corbet, M.D., A. J. Douglas, M.D., Ross Millar, M.D., G. D. Stanley, M.B., M.P., Lieut.-Colonel A. McPhee Warner, M.D., R. E. Wodehouse, O.B.E., M.D., R. A. Worthington, M.D., A. T. Macnamara, M.D., G. B. Horrocks, M.B., Captain F. H. R. Heath, M.R.C.S., S. L. Dawkins, M.B., Captain M. G. Louisson, M.B., F.R.C.P.

Serving Brother.—C. Gardiner-Hill, M.B., Lieut.-Colonel N. Maclaren, M.B., F.R.C.S., R.A.M.C.(T.A.), Colonel C. H. S. Redmond, T.D., M.B., A.M.S., Major M. MacEwan, D.F.C., T.D., M.B., F. L. Newton, M.B., W. T. Thomson, M.R.C.S., G. P. Huws, M.B., H. E. Thomas, M.R.C.S., A. B. Hudson, M.D., J. H. R. Bond, M.B., Lieut.-Colonel R. M. Gorssline, D.S.O., M.B., L. H. Leeson, M.D., Major S. R. Gibbs, M.C., T.D., M.R.C.S., W. H. Vickery, F.R.C.S., Major T. Russell, O.B.E., L.R.C.P., A. S. Watson, M.B., R. J. L. Sladen, F.R.C.S.

Serving Sister.—Mrs. Grace H. G. Dundas, F.R.C.S.I.

THE HARVEY MEMORIAL TOWER

BY

SIR JOHN ROSE BRADFORD, BT., M.D.

On Friday, July 7th, at 3.30 p.m., Lord Dawson of Penn, President of the Royal College of Physicians, will lay the foundation stone of the new tower of Hempstead Church, Essex, which is now in process of reconstruction. This tower will in future be known as the Harvey Tower, and will be a visible and worthy memorial to the memory of William Harvey.

Hempstead and its church are closely and peculiarly associated with William Harvey and the Harvey family. The church is beautiful and of very considerable historical interest as an example of the Early Gothic building of the Middle Ages, dating as it does from the fourteenth century; but to members of the medical profession, and indeed to all workers in biology, there is surely a most direct and moving appeal in thus associating the memory and the name of the great exponent of the experimental method with the reconstruction of a tower that will in future be known as the Harvey Tower.

The Harvey family had many distinguished members in various walks of life, and their mortal remains lie in the vault under the Harvey Chapel built by members of the family who were landowners in the vicinity, and here in 1657 William Harvey was interred, and his body remained undisturbed until 1883.

In 1882 the church tower, after developing cracks in its upper parts, fell suddenly during the night of Saturday, January 28th. The collapse was due in all probability to some weakness in the upper parts of the tower, since the excavations recently made in the course of the reconstruction have revealed that the original foundations are sound, notwithstanding their great age. The fall of the tower fifty years ago produced a result that it is to be hoped is not often to be seen, since the smallness and the comparative isolation of the parish of Hempstead were such that it was not possible to collect sufficient funds to repair the damage. It is difficult to describe adequately the scene of desolation in the churchyard, encumbered as it was with the accumulated debris of the fallen masonry and with the fallen great bells of the church, that most fortunately were not seriously damaged. All that could be done, in addition to some urgent temporary repairs, was to collect and stack the stones and flints with the hope of some day rebuilding the tower.

The Harvey vault, with lapse of time, also fell into disrepair, and in 1883 the College of Physicians felt that it was not fit that the remains of the immortal Harvey should be so little cared for, and they removed the leaden shell containing his body from the vault and placed it in a marble sarcophagus in the Harvey Chapel of the church, where it now rests. Thus Harvey's remains have been treated in a dignified manner worthy of the greatness of the man.

During the last few years a committee representative of the medical profession and of the parishioners of Hempstead has striven to raise funds to restore the tower as a memorial to Harvey, and has obtained altogether some £3,000 in cash and promises. This sum is insufficient to restore the tower to its full height, and the rebuilding of the ringing room and of the belfry will have to be postponed unless a further sum of £2,000 can be obtained. Nevertheless, the building of the tower up to the level of the ringing room floor will be a vast improvement on the existing conditions, and it is to be hoped that it will afford an inducement to others to make contributions to the fund, and so enable the committee to complete its work. Not only has the cost of the rebuilding

been much reduced owing to the fact that the great bulk of the masonry required has been provided through the care taken in the past to preserve the old stone and flints, thus avoiding largely the purchase of new stone; but in addition there will be the satisfaction that the restored tower will consist to a great extent of the old material.

The committee was fortunate in securing the services of Sir Charles Nicholson as architect, and his drawing of the restoration is exceptionally pleasing, and in complete harmony with the ancient church. In the course of the preparations for the laying of the foundation stone, not only have the old foundations been found in excellent condition, but in addition several interesting relics of a Norman church that stood on the same site have come to light, and have been examined by the Rev. T. B. Conyers Barker, the vicar of Hempstead, who describes "portions of Norman shafts with interlaced work, a cap which covered twin shafts, and two leopard heads inserted as labels over the doorway." Further, Mr. Conyers Barker mentions that six ornamental stones bearing heraldic shields will be replaced on each side of the doorway of the new tower and on the faces of the four buttresses. It is to be hoped that the occasion of the laying of the foundation stone will afford an opportunity for many to make donations and to enable the work to be completed.

THE CAMBRIDGE MEDICAL COURSE

AMENDED PROPOSALS

In the *Cambridge University Reporter* for June 17th (No. 2939) is published the amended report of the Syndicate on the Medical Courses and Examinations of the University. It will be remembered that in reviewing the proposals for a Medical Sciences Tripos at Cambridge we said: "Of the various proposals put forward exemption from the Second M.B. through the anatomy (modified for this purpose) and the physiology of the Natural Sciences Tripos would go far towards solving the main problem."[1] And this is, roughly, the conclusion arrived at by the Syndicate in its amended report.

The report states that the bulk of University opinion is against the introduction of a Medical Sciences Tripos, and that the Syndicate itself is of the opinion that it would be preferable if the necessary changes could be effected in the Natural Sciences Tripos. The Syndicate and the Natural Sciences Tripos Committee are now in agreement on the proposed changes, to which the Faculty Boards have given their general approval. If the Senate also gives its approval the introduction of a Medical Sciences Tripos will be unnecessary. The Syndicate remains unaltered in its conviction that the present duplication of courses and examinations for the Natural Sciences Tripos, Part I, and the Second M.B., Part II, must be abolished. The following proposals, whereby exemption of medical students from Parts II and III of the Second M.B. can be obtained through a modified Natural Sciences Tripos, have been formulated after consultation with the Natural Sciences Tripos Committee.

In the study of anatomy, under the existing scheme, the student spends his first two years memorizing the mass of topographical detail necessary for Part II of the Second M.B., and the last year in "getting up" the morphology and embryology required of him for Part I of the Natural Sciences Tripos. The Syndicate deprecates this artificial division, and holds that topographical anatomy and morphology and embryology should be taught together as one subject; and it advocates that the anatomy of the Natural Sciences Tripos, Part I, should consist of equal proportions of "scientific" (morphology and embryology) and topographical anatomy. Of the latter, less detailed knowledge will be required, and teaching will deal chiefly with the general architecture of the body, with more exact treatment of certain important areas such as the nervous system. The scope of physiology is to remain unaltered, but the Syndicate recommends that the chemical part of physiology be taught in the Department of Physiology, and that some of the biochemistry which is more directly related to the education of the medical student should be taught in the Department of Biochemistry. It is proposed that optional questions on pharmacology shall be included in the physiology papers of the Natural Sciences Tripos, but it is not intended that pharmacology should be a subject in Part I of the Tripos. The Syndicate recommends that the present course of pharmacology held in the Lent Term and Long Vacation should continue, and that the student should not proceed to the Third M.B. until he has attended this course (or an approved course elsewhere) and passed a *viva voce* examination at Cambridge. It is also suggested that opportunity should be given to the student to study pharmacology in conjunction with the physiology for the Natural Sciences Tripos, Part II, and that he should be allowed to substitute one or, when possible, two papers and a practical examination in pharmacology for one or two papers and the corresponding practical in physiology. Evidence from many resident and non-resident members of the University strengthens the Syndicate's opinion that general pathology and bacteriology should form a half-subject in Part I of the Natural Sciences Tripos. The Syndicate does not suggest, however, that candidates should be required to take pathology in the Tripos in order to qualify for the Final M.B., as pathology forms part of this examination. It is opposed to a student's studying pathology in his first year. Owing to the increasing importance of biochemistry in scientific research and medical practice it is recommended, with the concurrence of the Natural Sciences Tripos Committee, that biochemistry should be a half-subject in the Natural Sciences Tripos, Part I, and that medical students should be advised not to take it until their second year. To encourage those medical students who wish to offer chemistry as a subject in the Tripos, the Committee for the Natural Sciences Tripos has now agreed, at the request of the Faculty Board of Physics and Chemistry, to propose the introduction of two half-subjects in chemistry—inorganic and physical chemistry, and organic chemistry. Each half would include general chemistry, and the two halves together form the whole subject. The Syndicate has also proposed a half-subject in zoology adapted to the needs of the medical student in Part I of the Natural Sciences Tripos. The Natural Sciences Tripos Committee agrees that zoology might be divided into two sections, Zoology A and Zoology B, the former being a half-subject suitable for medical students and the two together making the whole subject. While it is admitted that psychology is becoming of increasing importance in medicine, the Syndicate does not regard this as a suitable subject for Part I of the Natural Sciences Tripos. It proposes, however, that the student should be allowed to study psychology in conjunction with the physiology of Part II of the Tripos.

GENERAL RECOMMENDATIONS

In order to proceed to the Final M.B. Examination via Part I of the Natural Sciences Tripos, the student who gets honours in the Tripos must have satisfied the examiners in anatomy, dissected the whole body, and have passed a series of practical tests to ensure that the dissection has been adequately carried out, and must also have satisfied the examiners in physiology. It may be noted that pharmacology and pathology are not compulsory Tripos subjects for such a student. The Syndicate allocates thirty hours a week to lectures and laboratory work in anatomy, physiology, and one other whole subject, or two half-subjects (twelve, nine, and nine hours, respectively); and this, it considers, will enable a "good" student who has passed the whole of his First M.B. before coming into residence to take the Natural Sciences Tripos, Part I, in three subjects at the end of his second year. The "average" student and the student who has done

[1] *British Medical Journal*, November 19th, 1932 (p. 936).

no science before coming up to Cambridge should spend three years over Part I of the Tripos.

It is therefore proposed that Parts II and III of the Second M.B. be abolished, that Part I (organic chemistry) be transferred to and become Part IV of the First M.B., and that qualifying examinations in anatomy and physiology be provided for those who have not offered these subjects in the Tripos, or who have not reached the standard required, although obtaining honours. This qualifying examination could also be taken by students not intending to read for honours, but who would proceed to the Ordinary B.A. degree: these students, however, will have to "*rely on some medical qualification other than the Cambridge M.B. Degree.*" (Italics ours.) The Syndicate wishes to make the degrees of M.B., B.Chir. "conditional on obtaining honours, or on reaching later an honours standard in a Tripos." It is "of the opinion that the Cambridge M.B. Degree should normally imply a high standard in the preclinical training in science, which Cambridge is peculiarly qualified to give, as well as a high standard in the final examination in clinical subjects." The Syndicate has also made provision for students who may wish to take up medicine after obtaining an honours degree in some Tripos other than the Natural Sciences. Such a student who has gained honours in any part of any Tripos would be allowed to proceed to the Final M.B. Examination after passing the first M.B. and the qualifying examinations in anatomy and physiology, after taking an approved course in pharmacology and passing the *viva voce* in this subject in Cambridge, and after having completed the dissection of the body and passed the necessary practical tests.

The Syndicate is strongly of the opinion that no clinical work should be done at Addenbrooke's Hospital during the three years' residence at Cambridge, which should be devoted exclusively to preclinical subjects; but it is anxious that the teaching of applied anatomy, biochemistry, pharmacology, physiology, and pathology should be developed in co-operation with the physicians and surgeons on the staff of the hospital. To ensure adequate clinical work it is proposed that a student should not be allowed to take both parts of the Final M.B. until three years, and one part until two years, after passing the last examination which qualifies him for the final examination. Modifications of the conditions for obtaining the M.D. are also put forward, as well as other recommendations.

England and Wales

International Congress of Orthopaedic Surgery

As already announced in these columns the second Congress of the International Society of Orthopaedic Surgery will be held in London from July 19th to 22nd; the president will be Professor Nové-Josserand of Lyons, and the secretary Mr. Harry Platt, surgeon in charge of the orthopaedic department of Ancoats Hospital, Manchester. The meetings will take place at the Royal Society of Medicine. After a general meeting on the afternoon of the first day, the president will hold an evening reception at the Langham Hotel. Proceedings will open on July 20th with an address by Professor Nové-Josserand on the general position of orthopaedics. This will be followed by a discussion on the general mechanism of joint movements, the first speakers being Drs. von Bayer of Germany, Delitala of Italy, and Scherb of Switzerland. In the evening there will be a reception at the Royal College of Surgeons. Tuberculous coxitis will be the subject for debate on the morning of July 21st, the first four contributors being Drs. Erlacher of Austria, Maffei of Belgium, Henderson of the United States, and Sorrel of France. In the evening there will be a dinner at the Dorchester Hotel. The morning of the last day will be devoted to short papers, the subjects including arthroplasty of the hip; hypertrophic osteopathies; a film illustrating the treatment of fractures of the spinal column; the pathodynamics of wrist and finger contractures; and gland biopsy as a means of diagnosing tuberculous osteoarthritis of the limbs. The afternoon will be spent in a visit to Alton. In connexion with this congress, tours are being arranged to Shakespeare's country, the West of England, and Scotland. Participation in the congress is limited to members of the International Society.

Epsom College

Lord Burnham, the president, was in the chair at the eightieth annual general meeting of the governors of Epsom College, held on June 23rd at the office, 49, Bedford Square, W.C. In announcing the result of the election of pensioners and foundation scholars, the president commented on the pains taken by the Conjoint Committee to elect as foundationers the most deserving boys who at the same time would appear to be the most capable of utilizing their great opportunity, and stated that the boys' fathers had practised in various parts of Great Britain: one in Glasgow, three in Lancashire, two in Yorkshire, one in Ireland, one in Sussex, one in Cheshire, one in Devonshire, and one was in the Indian Medical Service. The names of the successful candidates were:

Foundation Scholarships: Edward H. Couper, Hugh W. Macintyre, Anthony G. Quinlan, Robert S. Sunderland, Robert D. West, William J. Dunlop, William M. Pinder, George L. H. Steede, Peter B. Verver, Brian H. Harriss, Michael R. Tosswill.

Pensionerships: Mrs. Mary J. Lindsay, Dr. Herbert Blott.

Dr. R. Prosser White was elected a vice-president of the College in appreciation of his generosity in founding prizes for the study of French and German or Spanish. In presenting the annual report of the council the president asked the governors to join him in an expression of pleasure on learning that the honour of knighthood would shortly be conferred upon Dr. Raymond Crawfurd, the chairman of the council. Dr. Crawfurd then gave the governors an interesting summary of the works carried out at the College in the course of the past ten years, during which period the council had endeavoured to do what normally would have taken 100 years. The report was unanimously approved.

Mental Disease Research in Birmingham

The Joint Board of Research for Mental Disease of the City and University of Birmingham has issued its annual report for 1932–3, in which the chairman, Sir Gilbert Barling, calls attention to the increasing difficulties brought about by financial restriction. Little progress has been possible as regards the proposed central laboratories for the Midland districts and the provision of special research laboratories in connexion with the building of the new medical school of the University. An outstanding feature of the programme of work during the year under review was the continuance of the investigation of nasal sinus pathology with special reference to mental disease. The director of the research laboratories, Dr. F. A. Pickworth, contributed to the July, 1932, issue of the *Journal of Mental Science* a detailed description of the present position in this respect, including a collection of data from the existing literature and an account of original work.[1] In the *Journal of Laryngology and Otology* (1932, xlvii, p. 797) an article by him appeared on the influence of septic infection upon the cerebral blood supply, the hypothesis being put forward that the most important cause of dysfunction of the brain was to be found in the disturbance of the circulation following sepsis of the sphenoidal sinus. A necropsy on a case of post-lethargic encephalitis

[1] See *British Medical Journal*, December 31st, 1932, p. 1201.

disclosed irregularities in the sphenoids, with indications of old sepsis. The left antrum contained pus, and the mucosa was thickened. Brain sections also showed changes of considerable pathological interest. It may be recalled that there was a series of 100 specimens supplied by the Board to illustrate nasal sinus pathology in the museum at the Centenary Meeting last year of the British Medical Association. Another line of investigation continued by the Board involved the examination of thick sections of the brain for the quantitative amount of nerve cells present and the condition of the vascular supply. Pathological changes were detected in the smallest brain arteries in cases of mental disorder. In many instances the total loss of cells of the cortex was very remarkable, and could conceivably be correlated with dementia. By this intensive study also many infarcts were brought to light which would otherwise have escaped notice. The blood supply of the cortex was found to show great variation in local areas, which contrasted sharply with the even distribution in normal animal brains used as controls. A large number of catheter specimens of urine were examined for organisms on the supposition that saprophytic streptococci might have access to the brain; the number of positive findings was significant.

London Public Health Services

Most of the matters which are dealt with in the second volume of the annual report of the London County Council, 1931 (Public Health),[1] have been already recorded in these columns as they have arisen from time to time in the proceedings of the Council, but it is useful to have some complete picture of the great work for which the Council is responsible. Apart from mental institutions, the Council has under its management seventy-five hospitals, with 41,000 beds, and with a staff, including the ambulance service, of nearly 19,000. It is mentioned that during the year under review four conferences took place between representatives of the Council and representatives of the London Voluntary Hospitals Committee, and that the subjects discussed were not limited to those strictly defined under the Local Government Act, 1929, but were extended to include other matters of mutual interest, such as facilities for medical education. The achievements of the Council in regard to housing are recorded in the same publication. Up to the end of 1931 the Council has completed as part of its post-war programme 46,724 houses and flats, and the total estimated population of these "Council houses" is over a quarter of a million. The housing programme for the quinquennium 1931–5 was an ambitious one, contemplating the provision of 34,670 houses and flats, and the initiation of schemes for dealing with clearance areas affecting a population of 30,000; but it has been interfered with by the financial situation. The development of the estates known as Becontree and St. Helier (Morden) is being continued, but at diminished rates of production, and it is proposed to proceed steadily with the Council's settled programme of slum clearance and rehousing.

Livingstone College

Commemoration Day at Livingstone College, Leyton, E., was held on June 12th, when the Archbishop of York presided over a large gathering. In his sympathetic address the Archbishop said that even a short course at Livingstone College was of supreme value to all missionaries. Sometimes the missionary had to take a responsibility or to make decisions that he would rather leave to the qualified medical missionary, but at least he would know through his training at the College whether he could deal with the case or whether he must call in the doctor. Those who had been through even one month's course would have some knowledge of the way in which the missionary could deal with the misery that surrounded him in his work. If the societies would supply thirty students a year for the full course it would be possible to keep the college running without further demands on the beneficence of the general public or on any sort of missionary funds. The principal, Dr. Tom Jays, said that Livingstone College had been passing through difficult times since 1931, with lowered fees and a great shortage of students. The treasurer, Mr. R. L. Barclay, said that during the past year expenses exceeded receipts by £346, and this in spite of the utmost economy in management on the part of the Principal and Mrs. Jays, to whom a great debt of gratitude was due for their ability and self-sacrifice.

CORRESPONDENCE

Unqualified Practice and the Medical Curriculum

SIR,—Sir Ernest Graham-Little, in his letter in the *Journal* of June 24th, argues that the Medical Acts have failed to protect, commercially and politically, the registered medical practitioner, and that therefore it is not worth while exacting the severe tests now required before admission to the *Register*; further, that the money now spent is not well spent, because it does not produce corresponding privileges. He then states that teachers and students are acutely dissatisfied with the present required course, and supports this statement by quoting a resolution passed by a medical society belonging to one of the teaching hospitals, by another resolution passed by a student society which had had the matter argued before it (wisely or unwisely?) by a member of the staff of the school, and by a reference to the appointment of a committee in London to discuss the curriculum. (In parenthesis I remark that Sir Ernest appears to be imperfectly informed regarding the primary reason for the appointment of this committee.)

To meet the political disadvantages referred to, and the dissatisfaction thus illustrated, Sir Ernest propounds a scheme of a four-years' course which should entitle to registration under the Medical Acts; he does not suggest any reform of these Acts. It will not be disputed by anyone that periodic inquiry into the relations between what is taught and what is needed for service to the public is both wise and necessary, but it is a new proposition that the length and requirements of the medical course should be settled on the basis of the commercial value of registration. A reform of the medical course may be overdue, and the particular point which deserves attention is as to whether the courses as at present given have value in reference to practice; there is a suspicion in many minds that the enthusiasm of teachers has loaded the course with matter that has no such value, and also that certain traditions, now outworn, are still retained.

Sir Ernest Graham-Little appears to me to confuse two affairs which have little or no relation to each other, the one being the protection given to the public and the profession by the Medical Acts, the other the adaptation of teaching to the needs of practice. The defects of the first cannot be remedied by altering the curriculum, and the discussion of the latter should not be clouded by political considerations.—I am, etc.,

K. W. MONSARRAT.

London, W., June 24th.

The B.M.A. Nutrition Committee

SIR,—There was a phrase, complimentary to the British Medical Association, in the *Week-End Review* of May 27th, which some of your readers may well find disquieting. Referring to the recent correspondence in that periodical on the need for a dispassionate inquiry into healthy subsistence standards for the people of this country, and to the appointment to this end of "a strong committee by the British Medical Association," the editor wrote: "No doubt the B.M.A. committee will produce an exhaustive study which will supersede previous work within its field." How much time, I wonder, would a committee need for preparing such an "exhaustive" study? And, supplementary to that question, What, however perfect academically, would be the value of such a study to our unemployed *here and now?*

You yourself, in commenting on the need for an inquiry, remarked that "malnutrition may be more widespread than some people believe," and that "even the most confirmed optimists would not like to assert that the winter of 1933–4 will see any marked amelioration of conditions in the depressed areas of this country." May I suggest, then, that if the committee is as much concerned with aiding the public as with the scholastic aspects of its inquiry, it would do well to issue an interim *strictly practical* report at once, leaving itself free to make an "exhaustive" study at the unhurried pace and in the cold, disinterested temper that befits a body of scientific workers.

One other matter: according to the preliminary announcement in the *Supplement* to the *Journal* of March 18th, it was intended that the committee should consist of "a dietician, a physiologist, a practising physician, a school medical officer, a medical officer of health of an industrial area, and a statistician." As far as it goes an excellent combination; but would it not be a good idea to empanel a human being as well? The excellent report by the *Week-End Review* "Hungry England" Committee fell short, in my opinion, because its members, all experts, could hardly have tasted, let alone tried to live on, some of the foodstuffs they recommended for the nutrition of millions of people, children as well as adults, in this country.—I am, etc.,

London, June 19th. JOAN MALLESON.

Arthritis and Allied Conditions

SIR,—It was with intense interest that one opened the *British Medical Journal* of June 17th to study the report of the Arthritis Committee, which has been eagerly awaited, and which is in so many respects the model of careful analysis and judicious criticism that was to be expected from the patient collaboration of such a distinguished group of practitioners. Nevertheless, it came as a shock to an orthopaedic surgeon to find that the seventeen physicians on the committee had taken upon themselves to include in their report what one can only describe as a pocket-manual on the orthopaedic treatment of arthritis. This suggestion, that one of the most difficult branches of a great specialty can be satisfactorily dealt with in four columns, seems to me a most dangerous one to put into the minds of the profession at large, and one which should not be backed by the authority of the British Medical Association. The fact that not a single orthopaedic surgeon was a member of a committee dealing with diseases which at all their stages provide problems for the orthopaedic mind makes the matter still more extraordinary—or perhaps one should say more comprehensible!

If the orthopaedic aspect of arthritis was to be dealt with in detail, surely the rough draft of this section should have been submitted to an authoritative body, such as the British Orthopaedic Association? Alternatively, no one could have objected to a paragraph stressing the need for attention to the mechanical aspects of all joint diseases, and encouraging co-operation with the orthopaedic surgeon.

As it stands, the section on orthopaedics at once provides details of some methods and ignores others of the greatest value. While in the sections on vaccine treatment and dieting warnings are given as to the complexity of these subjects and the difficulties of correct dosage, conversely in the orthopaedic section the provision of a spinal support, the treatment of flat-foot, the application of traction to stiff fingers, and many other difficult and controversial matters are lightly dismissed as simple affairs, within the scope of any practitioner.

Personally, as a member of the British Medical Association for the last twenty years, I feel it hard that its funds should be used to broadcast a document whose effect for years to come will be to lower the status of my own specialty, not to mention any depressing influence it may have on legitimate sources of professional income. I trust that the document, as it stands, will not be thrust further upon the profession without some judicious pruning or annotating.—I am, etc.,

M. FORRESTER-BROWN, M.S., M.D.Lond.
Visiting Surgeon, Bath and Wessex Orthopaedic Hospital and County Clinics, Somerset, Wilts, and Dorset; Honorary Orthopaedic Surgeon, Eastern Dispensary, Bath.

June 18th.

*** The memorandum on which this section of the report was based was written by a distinguished orthopaedic surgeon and approved by another. A relatively large space was given to this section after considerable discussion because the committee recognized that orthopaedic surgery had an important but not exclusive place in the treatment of arthritis.

SIR,—The British Medical Asscciation committee's report on arthritis is really valuable, and a very clearly written summary. They have excluded specific arthritis, but I wish to mention in this connexion a peculiar form of syphilitic arthritis which must always be considered in making a diagnosis. In 1925, when I was in Vienna, Professor H. Schlesinger had two or three cases in his clinic at University Hospital which he named "arthro-lues tardiva." He had observed more than thirty cases since 1921; a brief description follows.

Arthro-lues tardiva is different from an ordinary syphilitic arthritis. This is a late form of lues, and there are usually no signs of syphilis in other parts of the body; no gummata in other parts. The skin, mucous membrane, nervous system, cardiovascular system, and the viscera are usually free from syphilitic invasion. This form is very similar to other sorts of arthritis, and shows varying clinical signs. The onset may be acute or insidious; fever, exudate, and deformity are sometimes present and sometimes not. The disease attacks one joint or several. Most of the cases occur in middle age, but sometimes in old age. The joints usually affected are the sterno-clavicular, sometimes the maxillary or intervertebral, joints. It affects both knee-joints, with effusion of fluid or a fungus-like growth similar to that of inherited syphilis. The ankle, elbow, and wrist joints are occasionally affected, but never the hip-joints. When the disease travels from one joint to another, usually the first joint shows no sign of relief—unlike rheumatic arthritis. Most of the patients have severe pain, especially during the night, and usually have some pain on active movements. Joint functions are fairly well maintained; ankylosis seldom occurs. X rays show damage of periosteum, cartilage, membrane, and ligament, but, strangely enough, one articulating surface usually remains unaffected. The Wassermann and precipitation tests of the serum are usually negative, but exudate from the joint cavity is frequently positive.

For differential diagnosis, when this disease starts like an ordinary rheumatic arthritis it can be easily detected, because it is completely unaffected by salicylates. It is easy to distinguish from tuberculous arthritis with a small dose of tuberculin, and from gonococcal also with vaccine and smears. It is not likely to be mistaken for gout, with its characteristic symptoms.

There is one definite pharmacological diagnostic method. Apply plenty of mercury ointment upon the painful joint covered with lint, and leave it so the whole night. If the case is arthro-lues tardiva, two different signs occur. Either (1) the pain, which has been so severe that the patient could not sleep (in one case even for a month), disappears like a miracle; or (2) the pain will increase in the first stage and relief occur after three or four hours or two days (Herxheimer). The second sign will be more manifest when mercury, bismuth, or arsenobenzol is injected. If arsenobenzol is used besides general and focal irritating symptoms a pain may arise in joints or bones which seemed healthy before. Anti-neuralgic agents have no effect on these pains, but intravenous sodium iodide relieves it. The treatment of this disease is, of course, careful antiluetic therapy. Arthro-lues tardiva has an extreme tendency to relapse.

This is a relatively rare disease, but with the foregoing facts in mind it should be easy to diagnose. Many of these cases actually have been sent to infirmaries permanently unfit for work owing to a mistaken diagnosis. I had experience of two cases during two years in Japan.—I am, etc.,

Hampstead, N.W.3, June 22nd. DENZABURO KATO, M.D.

SIR,—In the report of the B.M.A. Committee on the Causation and Treatment of Arthritis (*British Medical Journal*, June 17th) I find the statement that "a recent writer . . . has found evidence of abnormal sulphur metabolism in arthritis . . . but other workers have failed to confirm this." I should be very grateful to the writers of the report if they could tell me who are these other workers. In my extensive study of the literature on this subject—English, American, German, and French—I have found only confirmation of the presence of sulphur metabolism disturbances in certain chronic rheumatic patients. May I suggest that in writings of such importance, when there is a question of a technical point, references should be given—I speak, of course, of references to published work, because it is the only work that counts—otherwise statements are apt to be erroneous. All those who have studied the metabolism of sulphur in chronic rheumatism have found that it is disturbed, and this is confirmed by the marvellous therapeutical action of sulphur in the hands of those who know how to use that remarkable agent.—I am, etc.,

London, W.1, June 17th. A. P. CAWADIAS.

Chloroform, the G.P., and Midwifery

SIR,—I have been much interested in the letters relating to the general practitioner and midwifery, and enjoyed greatly the papers from Professor Munro Kerr and those who followed. I do not intend to intervene in this correspondence, except to say that it has been the principle of the Rotunda Hospital for over a century to train post-graduate students and nurses to conduct an obstetrical case in hospital as they would in a cottage. The technique and ritual of the institution work for this object. It is the letter on chloroform in your issue of June 17th (p. 1079), in which my name is mentioned, that necessitates these words.

My views on chloroform are as follows: (1) It is a pleasant anaesthetic. (2) It is a dangerous anaesthetic. (3) It is quite justifiable for the general practitioner or specialist to use it when he is thoroughly trained and takes the whole responsibility. (4) In a maternity hospital, where juniors of small experience *must* give some anaesthetics, a well-nigh fool-proof substance like ether is safer, and therefore should be used. The danger is borne out by two deaths from chloroform at the Rotunda during the early years of my Mastership; it is borne out by the occurrence of deaths in that magnificent institution the Maternity Hospital in Glasgow, which may be regarded as the home of chloroform. A note of these deaths will be found in the clinical reports of these hospitals, and they are not hidden. It is borne out by the opinions of trained anaesthetists—for example, Shaw and Beckett of Dublin—and of experienced obstetricians—for example, W. Gilliatt and T. M. Healy.

I have the greatest regard and respect for the work of the general practitioner. I am perfectly certain that Dr. Welsh will continue to give chloroform with safety, and so shall I. There is, however, great danger in its indiscriminate use, and the danger may occur very early in its administration. I trust I have made myself clear, as I do not wish to be drawn again into a correspondence on this subject. I should be delighted to have a talk or a personal correspondence with Dr. Welsh at any time.—I am, etc.,

BETHEL SOLOMONS,
Dublin, June 20th. Master, Rotunda Hospital.

SIR,—I am surprised at Dr. Solomons's reported statement that deaths occurred after even a few breaths of vapour of chloroform. With all due deference to Dr. Solomons I simply do not believe it. After long experience of the administration of chloroform in midwifery and surgical and dental practice I am convinced that practically all fatal cases are due to an overdose, though it must be acknowledged that the capacity of a few persons is limited; but so it is with all anaesthesia. So far I have administered chloroform at 1,626 confinements, no deaths resulting under it, and never the slightest cause for uneasiness, even though a midwife did assist at administering. My surgical and dental cases number 1,357, again with no fatalities under the anaesthetic, chloroform alone being used, and only in the rarest instance giving any concern. Dr. Welsh is right, and he can rest assured that all that is required is faith in chloroform (administered without the use of unnecessary gadgets) and in the administrator.—I am, etc.,

Cowdenbeath, Fife, June 19th. JOHN B. PRIMMER.

"New Treatments for Old"

SIR,—One could not reply point by point to Dr. W. N. Leak's letter in the *Journal* of June 24th (p. 1126) without taxing the patience of a very long-suffering editor, but I cannot allow the assertion that I regard the members of the profession as "gullible fools" to stand uncontradicted. I would not apply such an opprobrious epithet even to the ten thousand doctors who testified to the marvellous properties of "yadil." I know that a general practitioner is not necessarily a general paralytic, but he *is* generally preoccupied, and the pressure of his life prevents him from putting into practice those excellent precepts concerning controls, etc., which he has learnt from his teachers, even as it prevents him from developing that detachment which is so necessary for the formation of judgement concerning the facts collected by experience. Dr. Leak's little story is a case in point. I congratulate Miss Leak on her rapid recovery from bronchopneumonia, but having seen, as many other practitioners have seen, equally dramatic recoveries without any medicine at all, I think it would be wise to defer judgement as to the relation between the remedy and the recovery. This does not mean that I would deny that there might be a relation. Only fools deny possibilities in medicine. But without adequate controls, it is folly to make claims for any therapeutic measure.

Dr. Leak has waxed very witty over my suggestion as to the possibility of suppressing disease. The idea, of course, invites burlesque, but I could quote numerous cases, in my own practice and that of others, which would demonstrate to any reasonable man that the idea is not so ludicrous as Dr. Leak would label it. Dr. Leak has never seen it, but then he has never entertained the possibility of its occurrence, and so would probably not recognize it even if he did see it. I know quite well why guinea-pigs and cats are used, and know, too, that the object of the profession is to make sick people well. But I seem to recall that John Hunter, and many other workers, particularly in anaesthetics, have made *themselves* temporarily ill, and have thereby made a greater contribution to medicine than a vast sacrifice of guinea-pigs could have secured.—I am, etc.,

Liverpool, June 24th. F. B. JULIAN.

Genesis of Gall-stones

SIR,—We are anxious not to occupy your valuable space with a lengthy reply to Dr. Shiskin's letter in your issue of June 17th; *in fact*, her attitude in allowing Lord Moynihan to quote her results without the details being subsequently published protects her from either adequate appreciation or criticism of her work. Nevertheless, as presented, the work is, in our opinion, full of simple statistical fallacy, of neglect of fundamental facts, and of failure to separate her categories.

From the statistical aspect we still fail completely to understand why a group of normal figures should be divided into those below the average value, which are to be called "normal," and those above the average, which are to be called "high normal." This surely brings at once an entirely unjustifiable bias into any interpretation of analytical results. Dr. Shiskin does not appear to understand our remarks about exaggeration of ordinates. We made no reflection whatever on the accuracy of the plotting of the curve; we referred to the unusual scale adopted for the ordinates, which scale is exaggerated to emphasize pictorially the trend of the results, especially as the normal values are set almost at the base line.

We have emphasized over and over again the importance of estimating the plasma cholesterol in both free and ester forms, and that the presentation of total cholesterol values alone ignores the more interesting and informative changes in the free to ester relation which throw light on the underlying factors which govern cholesterol metabolism. Dr. Shiskin persists also in ignoring the wide range of values of plasma cholesterol in healthy individuals; surely it is absurd that she should consider the extremes of normal as constituting either hypo- or hyper-cholesterolaemia when they are, nevertheless, findings in normal subjects. It is indeed fairly obvious that the distribution of her own analytical results in both gastric and duodenal ulcer cases does not show the occurrence of hypercholesterolaemia, but only a perfectly normal distribution more typical of the wide range of normal values than those figures which she obtained from the study on nine men and three women only.

In cholelithiasis it is now quite useless to determine averages of total cholesterol values in plasma without regard to the different categories into which the cases fall—especially as separation by both chemical and clinical means is generally possible.

Lastly, it is obvious to anyone reading our letter that we were not criticizing Lord Moynihan for not having read in 1925 papers which were published at a later date, but were referring to his letter published in your issue of May 27th, 1933.—We are, etc.,

J. A. GARDNER.
H. GAINSBOROUGH.

London, W., June 19th.

Treatment of Combined Sclerosis

SIR,—In your issue of June 24th (p. 1091) Dr. L. J. Witts, discussing the treatment of subacute combined degeneration, writes: "I am not convinced of the value of massive doses of iron in subacute combined degeneration, as I have seen subacute combined degeneration develop in a woman who was having massive doses of iron for a microcytic anaemia." At St. Mary's Hospital we have obtained such uniformly good results from this treatment that it would be interesting to know exactly how much iron this patient was taking. In following up our series of cases for a period of over a year it has now been found that patients will relapse should the dose of Blaud's pill be lowered below 40 to 50 grains a day. In a few cases the dose has had to be maintained at over 100 grains a day to prevent a return of symptoms.

During a discussion of this treatment at a recent meeting of the Clinical Section of the Royal Society of Medicine one speaker mentioned that he had just seen one of Dr. Witts's cases of microcytic anaemia in which subacute combined degeneration had developed in spite of treatment with massive iron therapy. He went on, however, to say that the patient had only been having 45 grains of Blaud's pill a day, which in our series of cases may constitute a "relapse" dose. I should be interested to know if Dr. Witts has ever found the development of nervous symptoms during treatment with over 100 grains of Blaud's pill a day, since some cases appear to require this amount in order to maintain the improvement in their nervous symptoms. I mention this point because in one or two instances the importance of administering the full 150 grains has been insufficiently realized by other observers, and consequently the benefit derived by the patient has been lessened.—I am, etc.,

St. Mary's Hospital, W.2, June 23rd. WILLIAM SARGANT.

Hernia and Appendicectomy

SIR,—I have followed with interest the correspondence concerning hernia and incisions for appendicitis. There seems to be a very strong case for using the gridiron incision for all cases in which the diagnosis is tolerably certain and the right paramedian for all dubious cases. Working on these lines one finds that a gridiron incision seldom proves amiss when used for men, though a paramedian is not infrequently necessary for women and children. Additional help is often afforded by palpating the abdomen when the patient has been anaesthetized—a lump previously masked by rigidity is not uncommonly disclosed, and the appropriate incision chosen. The chief objections to this practice appear to be the possibility of missing the diagnosis when using the gridiron incision and the difficulty of access to an adherent retrocaecal appendix through a paramedian incision. Actually, by selecting the cases, little trouble occurs. When a gridiron incision has been made in error any other surgical lesion can usually be excluded by looking for marked excess of peritoneal exudate; by deciding whether the appendix is inflamed from within or from without; and by exploring with a finger.

On looking through from four to five hundred personal cases of acute abdominal disease I can only find one in which the patient definitely suffered as a result of a gridiron incision. I removed an innocent-looking appendix, and could find nothing else abnormal, but one year later the patient returned with an acutely inflamed Meckel's diverticulum, which had evidently been the cause of the trouble. On those occasions when a case of supposed appendicitis proves to be, say, a perforated peptic ulcer

or a perforated gall-bladder, it seems much better to close a small gridiron incision and make a paramedian in the proper place. For many other lesions an extended gridiron gives adequate access.

Another marked advantage of the gridiron incision is its excellence from the point of view of drainage, as it is so admirably adapted to the method of delayed suture (as advocated, for instance, by Wilkie, *British Medical Journal*, February 14th, 1931, p. 253), in which the superficial parts of the wound are left unsutured at least for the first few days. Since adopting this method of delayed suture for really bad suppurating cases I have found not only that the patient gets well more rapidly, and that the wound heals more quickly, but also that incisional hernia and weakness of the scar is actually less common than is the case when the wound is sutured round a drainage tube, or when stab drainage is adopted and the wound closed. In these circumstances an abscess forms in the wound, and the stitches have to be removed just when they should be tied.

Weak scars as the result of sepsis are common, and inguinal hernia occurring as the result of any special incision must be at any rate comparatively rare, so surely one's attention should be focused on getting a sound scar rather than on the possible sequel of an inguinal hernia! In order to insert a tube through Battle's incision, where the rectus has been retracted inwards, one must either have a kinked run for the tube or use an unusually stiff tube to keep the track straight, and so not only increase the liability to faecal fistula and adhesions, but also aid and abet the suppuration.—I am, etc.,

R. K. DEBENHAM.

Birmingham, June 18th.

Prophylaxis of Malaria

SIR,—Dr. A. L. Hoops, in an interesting article on the cure of malaria with atebrin (*Journal*, June 10th, p. 993), states that it has been clearly proved that quinine prophylaxis is a delusion and a snare. This is a sweeping statement, which needs, at least, qualification.

Quinine prophylaxis may or may not be of use in the East—I am not in a position to express an opinion. In West Africa, however, where malaria is almost exclusively subtertian, it has a definite place in the maintenance of health among the European community. There the majority of Europeans take five grains of quinine daily. It is the irregular or non-quinine taker who is continually getting malaria. The regular taker is not immune, but seldom suffers from malaria. I am convinced that they do not suffer from undiagnosed malaria, as for six years I have advised people going on leave to continue their quinine during the voyage (two weeks) only. If they have had malaria during the previous six months I advise a further two weeks' quinine. I have followed up as many cases as possible, and none have developed malaria in England. I have stopped or reduced my own prophylactic quinine three times (once after two years' freedom from malaria), and each time I developed malaria within three weeks. I continue prophylaxis for two weeks only after leaving the coast, and have never developed malaria in England.

Although a small minority, the irregular or non-quinine takers account for almost all the cases of blackwater fever. I, personally, have yet to see a case of blackwater fever in a regular quinine taker. Regular quinine is, in practice, good prophylaxis against subtertian malaria. In West Africa it has stood the test of time.—I am, etc.,

Pancreatitis in Mumps

SIR,—Dr. Cole's interesting letter of June 17th (p. 1080) prompts me to record a case which occurred in my practice in 1929.

A girl, aged 13, had a moderately severe attack of mumps, but without vomiting or abdominal pain: she had apparently made a satisfactory recovery when attendance was discontinued. A month or so later her mother brought her to see me, and I was astonished to find that from being a plump, well-developed girl she was now almost emaciated. Her urine was loaded with sugar. Her symptoms, in conjunction with an abnormally high blood sugar content, made it clear that she was suffering from diabetes. I sent her to the Manchester Royal Infirmary, where she was admitted as an in-patient, and after some weeks put on insulin. She now looks in perfect health, but if the insulin is reduced there is glycosuria, and a recent blood sugar estimation showed a percentage of 0.32 one hour after 50 grams of glucose. There is therefore little prospect that she will ever be able to discontinue insulin treatment without risk.

Though such a sequel to mumps is certainly rare, it is evident from this and other recorded cases that the condition of the urine during the attack, and in apparent convalescence, requires more attention than has generally been given to it hitherto.—I am, etc.,

J. STAVELY DICK.

Manchester, June 19th.

SIR,—Here's some more. Last winter a middle-aged male patient of mine had mumps. A week later he was afflicted suddenly with acute abdominal pains with tenderness over the pancreas, and urgent vomiting and pyrexia. For several days he was very ill; and convalescence, not yet complete, was accompanied by the passage of occult blood. About the same time a young man had almost precisely similar symptoms a week after starting mumps. He, however, passed no blood, and he got well quickly. Mumps does seem to be a malady of which to be wary!—I am, etc.,

FRANK G. LAYTON.

Walsall, June 25th.

Aetiology of Acute Rheumatism

SIR,—Dr. Aston Key's letter (*Journal*, June 17th, p. 1081) raised the question of the relation of dampness to the aetiology of acute rheumatism, though the importance of its association remains a mystery. Another factor which remains unsolved is the relation of rheumatism to what are called "growing pains." "Growing pains" mean something different to every observer (or else nothing at all), and may best be described as pains in the limbs susceptible of no other diagnosis—in other words, the diagnosis is a dump-heap of unexplained pains in a child's limbs. Observers are divided as to whether these pains are rheumatic manifestations or not, but the fact remains that many a case of heart disease develops as a sequel to what has amounted to nothing more, in the eyes of parents, than transient growing pains in a child.

An investigation into growing pains (taken as pains in the limbs which admit of no other diagnosis) has shown certain differences in the anthropological type from rheumatism, but in the question of damp houses there is a distinct parallel. *Out of 500 cases investigated at University* College Hospital in 1928, a history of "growing pains" having occurred was twice as common in children from damp houses as in those from dry ones, the figures being 24.3 per cent. in dry houses as against 48.3 per cent. in damp ones. This tendency may have some bearing on the relation of frank rheumatism, vague limb pains, and dampness.—I am, etc.,

Dyspepsia of Sympathetic Origin

SIR,—I have been greatly interested in the recent articles of Dr. F. C. Eve[1] and Mr. J. J. Robb[2] in the *British Medical Journal*. Both of these clinicians incriminate the sympathetic system as the cause of that dyspepsia which is due to a lack of relaxation of the sphincters and to sluggish peristalsis of the gut. Mr. Robb gives a very complete list of the causes of sympathetic disturbance, but omits one that is by no means rare—namely, malposition of one or more vertebrae and consequent irritation of the sympathetic. As has repeatedly been shown by E. F. Cyriax,[3] these subluxations often cause the symptoms and signs to which Dr. Eve and Mr. Robb refer. I would therefore suggest that the "small group where I have failed to demonstrate any lesion" mentioned by Mr. Robb be investigated with a view to detecting some spinal abnormality.

As regards treatment, both authors have tried atropine, Dr. Eve with success. It seems difficult to reconcile this use with the fact that atropine is not known to have any action on the sympathetic system, but only on the vagus. In any case the prolonged treatment that is necessary when medicines are employed can often be greatly shortened by a most simple procedure that anyone can adopt who has a little patience. Where there is spasm of the gut—for example, in the pyloric region or along the colon—this spasm, whatever its cause, can be relaxed by a gentle manual vibration on the spastic area, which is usually easily identified by touch. (This is by no means the whole of the treatment as I do it, but is its important central feature.) Now if this is done for ten minutes—say, every day for a week or so—the offending sphincter or piece of gut acquires once more its power to relax, and a permanent cure often results.

Naturally, when there is an obvious cause for the sympathetic disturbance, such as a chronic appendicitis or a misplaced vertebra, this treatment is unnecessary, but in the much commoner cases where the origin of the trouble is doubtful this symptomatic measure is often enough to secure a cessation of symptoms for many years. The full manual treatment of the abdominal sympathetic was described by E. F. and A. K. Cyriax in 1910,[4] and their experience during the last twenty years has confirmed them in their view of its great utility—an observation that I in my turn, though on many fewer cases, am once more corroborating.—I am, etc.,

London, W 1, June 6th. J. H. CYRIAX.

Metamorphosis of *Filaria bancrofti Cobbold*

SIR,—In the issue of the *Journal* of February 25th (p. 301) there is an interesting paper by Dr. P. Manson-Bahr on the history of British discoveries in tropical medicine. Owing, I have no doubt, to condensation, this paper hardly does justice to the discoveries of Dr. T. L. Bancroft, his part in filarial research being dismissed in the brief statement:

"The actual time-cycle development of the filaria in the mosquito was worked out first by Dr. Carmichael Low in 1900 on material sent to Manson by Thomas Bancroft, the son of Joseph aforementioned."

The great obstacle facing early workers on mosquito-borne diseases was the prevailing idea that female mosquitos only fed once and died after laying their eggs. This it was that prevented Manson, Lewis, and other early workers from discovering the full life cycle of the worm, and led them into erroneous conclusions concerning the mechanism of transmission from the insect to man. It was because of the same idea that Bancroft, in his earlier experiments with bred mosquitos, failed to find the more advanced stages seen by Manson in captured insects, a failure that puzzled him greatly. To use his own words: "It never dawned on me that my mosquitos were dying from starvation!" To my mind, the real genius of the work of the late Sir Ronald Ross and of T. L. Bancroft, working at the same time, independently, in widely separated parts of the world, was the realization that this entomological belief was untrue and the immediate experimental proof that mosquitos would live many days and feed many times.

Once he had discovered how to keep mosquitos alive for considerable periods the rest of the work was comparatively simple, and in a paper read before the Royal Society of New South Wales on June 7th, 1899, Bancroft described and figured the various stages of the larval filaria in the mosquito, giving the time of development as from sixteen to thirty-five days, according to season. He also described his methods of rearing and handling mosquitos. He did not see the larvae in the proboscis, and, in the body of the paper, suggested that infection was contaminative. However, in an addendum he pointed out that, as the full-grown larvae were killed by water, it was probable that they would be killed by the digestive juices, and he makes the following significant statement:

"It has occurred to me that the young filariae may gain entrance to the human host whilst mosquitos bearing them are in the act of biting. The entrance of warm blood into the mosquito may excite the young larvae, in consequence of which they . . . pass down the proboscis into the human skin."

In 1900 Dr. Low found the larvae in the proboscis of infested mosquitos which had been sent to London by Dr. Bancroft. Thus he completed the final chapter in the story, which was commenced by T. R. Lewis in 1872 with the discovery of the embryo filariae in the blood, continued by Joseph Bancroft in 1877 with the discovery of the adult worms, developed by Patrick Manson in 1878 with the discovery of the larvae in the mosquito, and brought to a climax in 1899 by the work of T. L. Bancroft.—I am, etc.,

Canberra, May 10th. I. M. MACKERRAS, M.B., B.Sc.

Cancer Families

SIR,—In your correspondence columns, rather more than two years ago, appeared letters on the high incidence of cancer in some families. The following history has come to my notice and seems to be worthy of record. With the death of my patient, Walter, the family is now extinct.

His mother died when about 34 of cancer of the "womb." His mother's two brothers both died of cancer of the liver when between 40 and 50 years old. (His father died of "senility" at 70.)

His brothers and sisters: Sarah died at 30, William at 38, Harry at 28, and Alfred at 30—all of cancer of the rectum. Joe died at 30 of "abdominal" cancer. Walter died at 48 of multiple abdominal secondaries (confirmed by laparotomy); the primary was not established.

—I am, etc.,

Obituary

FRANK JEANS, F.R.C.S.

Surgeon, Royal Infirmary, Liverpool.

We regret to announce the death at Harrogate, on June 21st, of Mr. Frank Jeans, whose outstanding ability as a general surgeon and urologist has made him well known and highly esteemed in Liverpool and London.

Frank Alexander Gallon Jeans, third son of the late Sir Alexander Jeans of Liverpool, was born at Derby in 1878, and received his medical education at St. John's College, Cambridge, Liverpool University, and King's College and St. Bartholomew's Hospitals. In 1904 he obtained the diplomas M.R.C.S., L.R.C.P., and two years later graduated M.B., B.Ch.Cantab. In 1907 he became a Fellow of the Royal College of Surgeons of England. After a term as house-surgeon to Sir William Mitchell Banks, he was appointed assistant surgeon to the Royal Infirmary, Liverpool, in 1909, and was elected honorary surgeon in 1924. His work at the Royal Infirmary was one of the main interests of his life. He was also consulting surgeon to the Hoylake and West Kirby Cottage Hospital, and the Waterloo and District General Hospital. For many years he maintained a close connexion with the University of Liverpool, where he had previously held a scholarship in surgical pathology and had been a demonstrator in anatomy. He was subsequently appointed lecturer in clinical surgery. A vice-president of the Liverpool Medical Institution, he was very active in the work of that society.

Soon after the outbreak of war in 1914 Jeans was placed in charge of the surgical division of the Liverpool Merchants' Mobile Hospital, with the temporary rank of Major, R.A.M.C., and served with it in France until the end; in 1916 he was appointed senior surgeon to the unit.

His special interest in urology brought him into considerable prominence, and he acted as consultant in this respect to the Liverpool Medical Research Organization. The position he held in the eyes of his colleagues in the specialty was proved by his election as president of the Urological Section of the Royal Society of Medicine for the session 1929–30.

Frank Jeans was the possessor of a lively wit and a great gift of fluent speech, which he could adapt to suit any occasion, ceremonial or informal. He was a welcome guest at social functions of all kinds, and a popular lecturer who marshalled his facts clearly and drove them home with humour appropriately introduced. As a teacher, at the bedside or in the lecture room, Jeans's vivid personality and gift of incisive phrase combined to impress his words upon the student's memory. He shone especially as an after-dinner speaker. A keen lover of music and the drama, he brought to social life a zest for its enjoyment which was infectious. His wife, who had been very active in Red Cross work during the war, died in 1928. He leaves a son and a daughter. He was for many years a member of the Lancashire and Cheshire Branch of the British Medical Association.

His death at the height of a brilliant career is deplored by a very wide circle of colleagues and friends.

THE LATE MR. HAMILTON RUSSELL

Mr. C. H. FAGGE writes:

News has just reached me from Melbourne of the passing of Hamilton Russell. Our first personal contact was a walk across Edinburgh when the Association of Surgeons met there in 1921. Last year one of the first faces I recognized on arrival in Melbourne on the night express from Adelaide was that of Hamilton Russell, who paid me this honour in spite of the early hour and his ambulatory difficulties. I saw him daily during my visit, when he was ever helpful with a word of encouragement or appreciation. One evening, in the house of another surgeon, the Council of the Royal Australasian College of Surgeons were meeting me at dinner. Hamilton Russell came in, and was persuaded to sit down at the piano, and I am sure we all were sorry when dinner was announced. One of the extraordinarily powerful features of medicine in Melbourne is the character of its senior representatives—Sir Richard Stawell, Sir Henry Maudsley, R. Hamilton Russell, Julian Smith, and Sir James Barrett are names which come to my mind: any one of them can ill be spared. The gentleness and humility of Hamilton Russell's personality, the sweetness of his smile, and his pathetic cheerfulness, in spite of physical pain and its limitations, endeared him to everyone; though doubtless in his modesty he would barely admit it even to himself. Those of his homeland who knew and loved him extend the hand of sympathy to his friends in the land of his adoption.

Sir G. LENTHAL CHEATLE writes:

The motor accident in which Hamilton Russell was killed deprived Australia of a man whose clean, wholesome, and active life was an example to manhood. His exceptionally handsome, refined, and attractive face was a mirror of his mind. None who knew him could fail to realize from the look of that striking head that he was imbued with a terse, blunt honesty; yet the spontaneity of his merry, never boisterous, laugh, the sincerity of his genial welcome, and the charm of his presence can never be forgotten. His detached and aloof expression might have led one to suppose its possessor incapable of bearing down heavily on things he considered wrong. This supposition was immediately exploded when one of his friends or juniors was not attaining his own high standard of correct conduct. Russell had an eclectic and meticulous taste in music, morals and dignified behaviour, and any thing that offended that taste met with a sharp and peremptory reminder that such things should be neither done nor said. This influence was very salutary to those who looked upon him as an Admirable Crichton, and it was also decisive when applied to impressionable youth. By all accounts we received from his friends and admirers in Australia this influence on younger people was maintained in the country of his adoption. He was also a little dogmatic in his method and manner, but all knew that he spoke truth, and it made a lasting impression in moulding our characters. He never told us why he was going to leave England, but we knew that he went to the beautiful climate of Australia to escape from a fear of tuberculosis. It is good to know that in Australia his integrity and professional ability were as highly appreciated as they would have been had he remained in London. There would have been no opposition to his election on the staff of King's College Hospital. He was house-surgeon to Lister, but not the last one. He was followed by five others.

Russell remained a bachelor. He had friends whom he loved as deeply as they loved him; but probably his greatest companion in life was his piano. Wherever he was a piano acted as a magnet to him, and after a time he would wander up to it and begin to play, always classical music. Whether his notes were always correct I am unable to say, but he never played from score. Although Russell had retired from active practice his colleagues realized the intense interest he continued to take in the surgical work going on around him. Attractive influence of this kind would be of value and would make itself felt in any country where it existed. Australia will miss him equally with his friends at home.

Dr. GEORGE BRADLEY HOWE of Stalybridge, Cheshire, died on June 15th, after an illness lasting about five months. The son of the late Dr. John Howe, he was born in Marple in 1865, and was educated at Epsom College and Owens College, Manchester. He obtained the L.S.A. in 1888 and the M.R.C.S. in 1892. In the latter year he went to Stalybridge as an assistant in the practice to which he ultimately succeeded. Since 1903 he had been district medical officer for that locality, and a few years later was appointed public vaccinator. He became school medical officer in 1925, and played a considerable part in building up this work on a sound and effective basis. He retired from this post in 1931, when a whole-time medical officer was appointed. For three years he was a member of the town council, retiring in 1901 ; two years later he was placed on the commission of the peace in recognition of his long and devoted service. He was one of the original members of the Stamford Golf Club and the first winner of its Cheetham Cup. A keen sportsman in his earlier life, Dr. Howe did all in his power to promote local cricket and tennis clubs in his later years. He had been a member of the British Medical Association since 1895, and was chairman of the Hyde Division in 1922. His wife died last year, and he is survived by six daughters.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons this week read the Metropolitan Police Bill a third time and the Sea-Fishing Industry Bill a second time. The vote for the Mines Department was down to be debated.

The Rent and Mortgage Interest Restrictions (Amendment) Bill and the Unemployment Insurance (Expiring Enactments) Bill passed through committee of the House of Lords, and the Blind Voters Bill was agreed to on report. The Finance Bill was read a second time and the Commons' amendments to the Pharmacy and Poisons Bill were down to be considered by the Lords.

The University Spurious Degrees Bill was down for the committee stage in the House of Lords on June 29th, but its withdrawal was expected. An agreed Bill may be substituted.

The Juries (Amendment) Bill was introduced in the House of Commons on June 20th by Mr. Holford Knight, and read a first time. One of its provisions would delete from the Rules of Court under the Sex Disqualification (Removal) Act the exemption from jury service of " any women who are for medical reasons unfit to attend." It would substitute words: " Exempting from attendance as jurors any person to whom special hardship would be caused on account of physical unfitness or business or household considerations."

On June 26th the Manchester Royal Infirmary Bill, which has been changed from the Manchester Corporation Bill, came before the House of Commons. On the motion of the Chairman of Committees, the Standing Orders were suspended, and the Bill was read a second time.

On June 26th the second reading of the Middlesbrough Corporation Bill, which contains clauses for the compulsory notification of infectious disease, was objected to, and postponed accordingly.

The Essex County Council Bill, which has passed through the House of Lords, was down for second reading in the House of Commons on June 26th, but objection was taken, and the Speaker announced that the second reading would be set down for the evening of June 28th.

Department of Health for Scotland

The Estimates for the Department of Health for Scotland in the year 1933-4 came before the House of Commons in committee on June 22nd. They included the grant-in-aid of the Highlands and Islands Medical Service and grants-in-aid of benefits and expenses of administration under the National Health Insurance Acts. Mr. A. N. SKELTON, who introduced the Vote, said that houses completed in Scotland in 1932 numbered 15,818 ; houses under construction at December 31st last, or approved and not constructed, numbered 30,777, the highest figure reached in Scotland. In the five months since that date tenders had been approved for 3,739 slum clearance houses. Local authorities in Scotland were responding fully to the task of clearing the slums. He was not satisfied with the figures for public health. Maternal mortality went up from 5.9 per 1,000 in 1931 to 6.4 in 1932. It had increased steadily since 1855—a mysterious phenomenon, not confined to Scotland. The Department had made close investigation into a number of maternity cases, but the doctors said it must supplement these with the records of all cases. In the middle of December, 1932, the Department instituted an investigation, to extend over six months, into every childbirth in Scotland. That period had just closed, and he believed they would have data more complete than existed elsewhere. Infant mortality figures for 1932 were 86 per 1,000, or 4 per 1,000 above the figures for 1931 and one above the average of the last five years. For a long period of years Scottish infant mortality had been definitely higher than English. Medical experts were not clear about the cause, but he thought the weather should be taken into account. Analysis of the English figures showed that, broadly speaking, infant mortality increased as one went North. In Northumberland and Durham the figures were almost exactly comparable with the Scottish figures. Ten years ago Sir Leslie Mackenzie came to the tentative conclusion that there was some relation between the climate and infant mortality. Not the intensity of the climate, but its variability was its evil influence on the very young. The only feature with regard to infectious diseases to which he drew attention was that last year an epidemic of scarlet fever in Scotland brought the cases from 18,000 to 28,000. When scarlet fever spread to Shetland the local authorities made available to all private practitioners means of immunizing their patients. He proposed to follow up the question whether more could be done in preventing infectious disease. In Scotland one inspection of the dairy herds annually by veterinary officers was statutory. Many counties had three. These resulted in earlier detection of the tuberculous cow and earlier elimination of the risk of infection.

Mr. DUNCAN GRAHAM remarked that of 87,903 houses inspected in Scotland last year one-sixth were admitted by the Department of Health to be unfit for human habitation. The Labour Opposition contended that single- or two-roomed houses were slums, whether in town or in country. Any doctor worthy of the name must describe these houses as unfit for human habitation. The main cause for the increase in maternal and infantile mortality was poverty. Medical authorities had stated that the infantile mortality rate was one-third in the middle classes of what it was in the ordinary working classes. In the mining villages it was as high as 260 per 1,000. Medical benefit should be secured to unemployed persons, who were threatened with the loss of it at the end of this year. He and other members for Lanarkshire had met the county medical panel committee, including representatives of the doctors, and it had expressed strong feelings on the proposed change. Doctors in the rural areas of Dumbarton, Renfrew, and Lanark should not be asked to make any more sacrifices. He urged that the National Health Insurance Act should be modified to ensure that the State paid the cost of medical attendance in the cases of men unemployed. Sir ARCHIBALD SINCLAIR welcomed the inquiry into the health services. He asked what proposals had been submitted to local authorities for the improvement of maternity services, and whether they were being put into operation. Why was the grant for the training of midwives and health visitors reduced from £3,200 to £2,700? An increase in the consumption of milk would be one of the best means of improving the diet of the people, but to do that they must eradicate tuberculosis by such means as those successfully employed on a large group of farms in Ayrshire.

Mr. MCGOVERN moved a reduction of the vote. Mr. DAVID MASON said the unemployed persons who, if the law did not change, would lapse from national health insurance medical benefit on December 31st were about 20,000 in Scotland, and 100,000 all told. Mr. HENDERSON STEWART contended that

in any county of Scotland about 50 per cent. of the cottages in the villages could be improved by the application of the Housing (Rural Workers) Act. The number of houses so improved declined last year. Rickets increased in Scotland last year, and there was a decrease in population. Part of the blame for the fall in the general health of the Scottish people rested with those responsible for housing. Mr. R. W. SMITH said the increase in maternal mortality was due principally to puerperal sepsis. Was it more common to have this infection in institutional treatment? There was a considerable increase last year of births in institutions as compared with previous years. The present policy of the Department was to encourage institutional treatment of maternity cases. Would it not be wiser to encourage home treatment till they were quite certain what they were doing?

Mr. SKELTON, replying to the debate, said the figures Mr. Smith gave on puerperal sepsis were undoubted. When the evidence of the six months' special investigation was before the experts they might trace the causes of puerperal sepsis and tell whether it was more frequent in institutions. In their opinion on the causes of infant mortality the medical profession and the medical advisers of the Department were not conclusive, but variability of type seemed a strong factor. He thought hard times also an important factor. The question of medical benefit for the unemployed would come before the Cabinet. He thought that by administrative manipulation the benefit might be continued.

Mr. McGovern's amendment was defeated.

A discussion followed on the Vote for public education in Scotland, and on the Vote for the salaries of the Scottish Office.

Road Traffic (Emergency Treatment) Bill

In the House of Lords on June 22nd Lord MOYNIHAN moved the second reading of the Road Traffic (Emergency Treatment) Bill, which, he explained, Lord Halsbury had helped to draft. It sought to redress iniquities which were admitted, considerable, and increasing. The experience of the medical profession was that since the Road Traffic Act, 1930, the public confidently believed that under the compulsory system of third-party insurance payment was made almost automatically to the out-patient departments of hospitals and to general practitioners who rendered emergency treatment. That view was inaccurate. By the help of the British Medical Association he had been able to ascertain with comparative accuracy that not more than one medical man in five who was responsible for emergency treatment received either verbal acknowledgement or payment for the services rendered by him. When a payment was secured it was only with difficulty, because the owner of the motor car lived at a distance from the place of the accident and because the insurance companies advised that any payment made by the owner of a motor car which had caused an accident admitted the guilt of the driver. The medical man who provided this aid had to supply drugs, dressings, and appliances, and might have to renew the furniture, couch, or carpets of his surgery The medical profession rendered an immense amount of gratuitous services to the public. He found roughly that 60 per cent. of the work that he had done in his profession had been unrewarded financially, and he was not distinguished from colleagues similarly placed. All the important services rendered by his profession in connexion with the voluntary hospitals, particularly the teaching hospitals, received no financial, or only a slight financial, reward. If ever there had been unanimity in the medical profession about an injustice to practitioners it was in connexion with emergency treatment. He could not say there was resentment in the profession, but dismay existed. The Road Traffic Act, 1930, made no provision for payment for services rendered in the out-patient departments of the hospitals, though these might be expensive to carry out and might save the insurance companies money by timely treatment. He was not concerned with in-patient treatment, though the loss there was considerable. It was computed that 35,000 out-patient treatments were given in a year, at a cost of £12,000, and not one penny of that sum was returned to the hospitals. The Bill proposed a maximum fee of three guineas for treatment. King Edward's Hospital Fund suggested a larger sum, but that would include massage given, if necessary, after the first attendance. A preliminary demand should be made on the driver of the motor vehicle which would pay for the out-patient department treatment and for treatment given by the general practitioner. To secure this the sum paid for a driver's licence might be increased from 5s. to 7s. 6d., or the insurance premium increased by the same amount. There were 2,800,000 motor licences in the country to-day, and a charge of 2s. 6d. on these, or on the premium charged by the insurance companies, would more than suffice for the payments he proposed.

Lord HALSBURY asked the House to support the second reading. The Bill referred to "emergency treatment" and not to "first aid," because the St. John Ambulance Association said that "first aid" ceased at the moment the practitioner came in. The Bill dealt with emergency treatment, and not with the subsequent treatment which might be given in hospital. Lord Moynihan and the British Medical Association had put their claim with extraordinary restraint. The Bill should be modified in committee to cover the case of the motor car which ran over someone and drove on without stopping. Lord ONSLOW, Chairman of Committees, supported the Bill. He believed that there were 150,000 road accidents a year, and the cost should be borne by the motoring interest as a whole. At present the burden of emergency treatment fell on the doctors, the hospitals, the ambulance, and the general public. Disputed claims for treatment could be settled in a court of summary jurisdiction with an appeal to the county court. Lord DANESFORT welcomed the Bill, and praised the voluntary services of the medical profession. Lord BERTIE OF THAME thought the word "road" should be omitted from the Bill, as being too narrow, and that the Bill should be entitled the Motor Vehicle Traffic (Emergency Treatment) Bill. Lord KINNOULL recounted a case where an insurance company made provision for the medical expenses of a person who had been knocked down, but this person spent it, and did not pay the doctor or the hospital anything. There was no way of forcing such a person to pay. Lord LUKE informed the House that the King Edward Hospital Fund had combined with the British Hospitals Association to give evidence to the committee over which Lord Iveagh presides (the committee considering the Road Traffic (Compensation for Accidents) Bill), and had submitted an amendment to that committee to meet the hospital view. If Lord Moynihan's Bill also went to that committee it would be unnecessary for the Fund and the Association to give evidence again. Earl BUXTON, for the Liberal peers, supported the Bill, and said he had never heard a private member's Bill moved in a more able manner. The vast bulk of road accidents happened to persons who could contribute something for the medical help they received. Three guineas ought to be the minimum payment. Viscount KNUTSFORD thought that only professional aid should be compensated, and that the extra tax should be put on the driver's licence. That would bring in £300,000 a year, which Lord Moynihan and the British Medical Association must agree would more than compensate doctors for first treatment.

The Earl of PLYMOUTH, for the Government, noted that the Bill provided that the remuneration should be recovered from the owner of any vehicle involved, irrespective of fault or negligence, and that an additional sixpence per mile should be recoverable for every mile above two which the medical practitioner had to travel to the accident. In such cases medical practitioners and hospitals had a serious grievance, particularly small cottage hospitals near main roads. It was difficult to find a suitable remedy. Lord Moynihan originally suggested a central fund contributed to by insurance companies. He had departed from that, and proposed to place liability upon the owner of any vehicle involved in an accident, irrespective of fault or negligence. That ran counter to the established principles of jurisprudence. The Bill would fasten liability on a man for something for which he might not be in any way responsible, but gave him no opportunity of recovering from the person who was actually negligent. An additional levy of 2s. 6d. on motor licences, producing about £350,000 yearly, would almost certainly result in reduction of the voluntary payments now made to hospitals. He also thought it possible that many owners would ignore small accounts sent in by doctors of whom they knew nothing, and that, to recover, the doctors or hospitals would have to make out particulars of claim, go to a county court, and pay various fees. If the Bill went further, the Government would

have to ask for modification of Clause 5, dealing with vehicles owned by the Crown. Though he made these criticisms he agreed that medical practitioners and hospitals had a genuine grievance and that the subject called for further investigation. The Earl of HALSBURY explained that if the Bill became law any money paid by the owner of a vehicle would be recoverable, under Common Law, from the man really responsible for the damage. To incorporate this in the Bill was unnecessary. Lord IVEAGH, as chairman of the committee to which the Bill would be referred, said that committee would welcome it and Lord Moynihan.

The Bill was read a second time without a division and referred to the same Select Committee as that to which the Road Traffic (Compensation for Accidents) Bill stands referred. The committee was given power to consolidate the two Bills, and Lord Moynihan was added to the committee.

The Select Committee of the Lords on the two Road Traffic Bills was called to consider them on June 29th.

Cost of Public Mental Hospitals.—Replying to Mr. Grenfell on June 22nd Sir HILTON YOUNG said that a figure of £500 which appeared in the report of the Board of Control for the year 1931 was the Board's estimate of the capital cost of providing a bed in a mental hospital, and was not the estimated cost of each inmate of a mental hospital per annum. The annual cost of upkeep of the public mental hospitals and maintenance, supervision, and treatment of patients was not £70,000,000 in 1931, but approximately £8,000,000, which was defrayed from rate funds. In 1932 this figure was slightly reduced, though the number of patients increased by about 1,900. The suggestion that inmates for whom detention could not be proved to be necessary should be accommodated in hostels run on a hospital footing to save expense was impracticable. The preventive treatment of such cases needed resources of staff and equipment unobtainable in hostels under whatever central system of control they might be placed.

Europeans and Indians in the I.M.S.—On June 26th Sir S. HOARE, replying to the Duchess of Atholl, stated that in 1922 there were 326 Europeans in the Indian Medical Service (Civil) and 35 Indians, making a total of 361. In 1932 there were 195 Europeans in the Indian Medical Service (Civil) and 97 Indians, a total of 292.

Report of Royal Commission on Lotteries.—Mr. DOUGLAS HACKING stated on June 22nd that the Government had not yet been able to give careful study and attention to the Report of the Royal Commission on Lotteries. The Home Secretary could not give any undertaking that it would be possible to introduce legislation in the near future to deal with any part of the field covered by the recommendations of the Commission. Mr. Hacking added that he did not suppose legislation was possible during the present session.

Medico-Legal

INFANT BLINDED IN HOSPITAL

At the Liverpool Assizes, before Mr. Justice Atkinson, on June 21st, an infant, Ivy Greta, daughter of John Lee of Birkenhead, claimed through her father damages against the Birkenhead Corporation, Dr. R. A. Grant (medical superintendent of the infirmary), and Nurse M. O. Parry, on account of an accident sustained in the hospital ten minutes after her birth whereby through the application of nitric acid, presumably instead of silver nitrate solution, the child was blinded for life. After a consultation in the judge's room it was announced that the case had been settled. Mr. Goldie, K.C., who appeared for the child, withdrew all allegations against the corporation and Dr. Grant. He said that this terrible accident was in no way due to any breach of duty by the doctor. The corporation had met the case generously. The child would go to a sunshine home for blind babies, would be educated, and later, as far as possible for a blind child, trained for a profession. If unable to obtain employment, in which respect the corporation would do its best, the maximum amount under the Blind Persons Act would be paid, without any obligation on the parents or relatives to contribute. Mr. Gorman, K.C., for the corporation, said that the terms now accepted were offered some months ago. This was no eleventh-hour offer on the part of the corporation. Here was a terrible harm done to the child of a Birkenhead ratepayer, and the corporation felt it a duty to see the child through life. Mr. Eastham, K.C., for Dr. Grant, said that there was no rule or regulation of the hospital with which Dr. Grant had not complied. At the time of the accident he was away on holiday. The action against Nurse Parry would be discontinued, and no order would be made against her as to costs. Mr. Justice Atkinson said that the corporation had acted very properly and generously. It was clear that all charges against the corporation and Dr. Grant were withdrawn. A very unfortunate slip made by the nurse had led to these terrible consequences, and he expected everybody was as sorry for the nurse as for the child.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on June 22nd the following medical degrees were conferred:

D.M.—C. W. C. Bain, A. M. Cooke.
B.M.—E. J. Baldwin.

The electors of the May Fellowship and Readership in Medicine have appointed Alexander Macdougall Cooke, B.M., of Jesus College to hold office until the first day of Michaelmas term, 1935.

UNIVERSITY OF LONDON

The title of Professor of Medical Entomology has been conferred on Dr. P. A. Buxton of the London School of Hygiene and Tropical Medicine, and that of Professor of Pharmacology on Dr. J. H. Burn, director of the pharmacological laboratory of the Pharmaceutical Society.

A university post-graduate travelling studentship of the value of £275 for one year has been awarded to A. Gilpin, M.D. (King's College Hospital), whose research will be on the physiology and pathology of the thyroid gland and on problems specially related to sporadic goitre and thyrotoxicosis, to be carried on in Freiburg and Vienna.

The university studentship in physiology, of the value of £100, has been awarded to H. A. Dunlop, M.D. (Westminster Hospital), who will carry on physiological research at King's College.

UNIVERSITY OF BIRMINGHAM

The Walter Myers travelling studentship has been awarded to E. J. Kerr, M.B., Ch.B., who will carry out research in Vienna.

Dr. O. Brenner has been appointed assistant in forensic medicine and toxicology, and Dr. A. V. Neale part-time demonstrator in practical pathology.

UNIVERSITY OF LEEDS

Professor Harold Collinson, C.B., C.M.G., D.S.O., M.B., M.S., F.R.C.S., has been elected to the chair of surgery, carrying the headship of the Department of Surgery, as from the beginning of next session, in succession to Professor Dobson.

Mr. A. Richardson, M.B., B.S., F.R.C.S., has been elected to the chair of clinical surgery as from October 1st.

Mr. E. R. Flint, M.B., Ch.B., F.R.C.S., has been appointed Director of Surgical Research in succession to Mr. Braithwaite.

Dr. S. J. Hartfall has been appointed honorary demonstrator in medical pathology.

UNIVERSITY OF GLASGOW

At the graduation ceremony on June 21st the following degrees were conferred:

LL.D. (HONORARY).—Professor William Blair-Bell, M.D., F.R.C.S., Past President of the British College of Obstetricians and Gynaecologists.

D.Sc.—Amy M. Fleming, M.D., Ch.B.

M.D.—Mary A. Griffin and D. R. MacCalman (with high commendation); J. Grant and A. W. Russell (with commendation); J. W. M. Alexander and F. W. Martin.

UNIVERSITY OF WALES

The Council of the Welsh National School of Medicine has made the following appointments, to date from October 1st, 1933: *Mansel Talbot Professor of Preventive Medicine*, R. M. F. Picken, M.B., Ch.B., B.Sc., D.P.H.; *Independent Lecturer in Materia Medica and Pharmacology*, R. St. A. Heathcote, M.D., Ch.B., D.Sc.

Medical News

H.R.H. the Princess Royal will lay the foundation stone of the Nurses' Home of the Hospital for Sick Children, Great Ormond Street, on Friday, July 7th, at 4 p.m. This ceremony marks the first stage in the reconstruction of the hospital.

The new children's wards and *x*-ray and electro-therapeutic departments of the Central Middlesex County Hospital at Willesden are being opened by Sir George Newman to-day (Friday, June 30th) at 3 p.m.

The fifty-first anniversary dinner of the West London Medico-Chirurgical Society will be held at the Trocadero, Piccadilly Circus, on Thursday, July 6th, at 7.30 for 8 p.m. The honorary secretary is Dr. W. S. C. Copeman, 15, Harley Street, W.1.

An address entitled "Medical Impressions of Soviet Russia" will be given by Sir James Purves-Stewart before the Paddington Medical Society at the Great Western Royal Hotel, Paddington Station, on July 11th, at 9 p.m.

The twenty-first anniversary of the coming into effect of the payment of contributions under national health insurance is to be celebrated on July 17th, when a luncheon will be held in the Hotel Victoria, Northumberland Avenue. Sir Hilton Young, Minister of Health, will be in the chair, and the principal guest will be Mr. Lloyd George. Representatives of the British Medical Association will be present. The actual day on which the national health insurance scheme began to operate was July 15th, 1912.

During the annual meeting of the Society of Chemical Industry in Armstrong College, Newcastle-upon-Tyne, there will be a general discussion on July 13th, at 10 a.m., on "How Science can Help the Nation to Produce More of Its Own Food," introduced by Dr. H. D. Kay and Mr. H. J. Page.

The next meeting of the Society for the Study of Inebriety will be held in the rooms of the Medical Society of London, 11, Chandos Street, W., on Tuesday, July 11th, at 4 p.m., when Dr. J. D. Rolleston will read a paper on alcoholism in mediaeval England. Each member and associate may introduce visitors. Tea and coffee at 3.45 p.m.

The fourteenth annual lecture conference of the Industrial Welfare Society will be held in the Wills Hall, Bristol, from July 7th to 11th. The programme includes lectures by Dr. J. L. Hammond, "The Historical Background"; Dr. Louis Segal, "Some Aspects of Welfare Work in Soviet Russia"; Mr. John Grierson, "Films in Industry"; M. Henri de Man, "Joy in Work"; The Hon. Mary Pickford, M.P., "Welfare Development in Industry"; and Mr. Elton Mayo, "Industry and Social Change." On July 10th and 11th visits will be paid to works in the neighbourhood.

The King Edward's Hospital Fund for London has made arrangements for tours of historic buildings of London under the guidance of distinguished experts. The following places will be visited: the Houses of Parliament (July 5th, 11 a.m.); Westminster Abbey (July 13th, 3 p.m.); India Office (July 22nd, 2.30 p.m.); Somerset House (July 25th, 2.30 p.m.). Tickets (7s. 6d. for each tour) can be obtained from the secretary, King Edward's Hospital Fund for London, 10, Old Jewry, E.C.2.

A week-end course in general medicine and surgery, arranged by the Fellowship of Medicine, will be held at the General Hospital, Southend-on-Sea, on July 8th and 9th. On July 7th, at 5 p.m., there will be an ante-natal demonstration at the Royal Free Hospital; on July 13th, at 4 p.m., a demonstration of *x*-ray films at 11, Chandos Street, W., and a course in proctology at St. Mark's Hospital, from July 3rd to 8th. Forthcoming courses include dermatology at the Blackfriars Skin Hospital, and practical pathology at the Brompton Hospital, July 10th to 22nd; ophthalmology at the Royal Westminster Ophthalmic Hospital, and urology at All Saints' Hospital, July 10th to 29th.

The twelfth annual conference of cremation authorities will be held in conjunction with the annual conference of the National Association of Cemetery and Crematoria Superintendents in London on July 10th, 11th, and 13th. A cordial invitation is extended to those who are interested in the question of disposal of the dead by earth burial or cremation. The opening meeting will be held in the Council Chamber at the Guildhall, with the Lord Mayor in the chair.

The French Orthopaedic Society has organized a congress to be held in Paris on July 17th and 18th, when demonstrations will be held in various hospitals, and be followed by a visit to Berck-sur-mer and London.

The final programme has now been issued for the sixth English-speaking conference on maternity and child welfare to be held under the presidency of Sir George Newman in the Friends House, Euston Road, N.W., on July 5th, 6th, and 7th. In conjunction with the conference a short clinical course for medical practitioners has been arranged for July 3rd and 4th, on behalf of the National Council for Maternity and Child Welfare and some of its constituent bodies, by the National Association for the Prevention of Infant Mortality in co-operation with the Maternity and Child Welfare Group of the Society of Medical Officers of Health. Those wishing to join the course should write at once to Dr. C. Isobel Wright, 121-131, Rosebery Avenue, E.C.

The thirty-eighth French Congress of Alienists and Neurologists will be held at Lyons, under the presidency of Dr. Lagriffe, from July 16th to the 22nd, when the following subjects will be discussed: the influence of psychological theories on psychiatric evolution, introduced by Dr. Répond; and tumours of the third ventricle, introduced by Dr. Desruelles.

The French Society of Restorative, Plastic, and Aesthetic Surgery adopted at its recent annual meeting a resolution condemning publications of all kinds on this subject emanating from medical practitioners and others whose scientific qualifications were inadequate. A warning was issued against consultations with unqualified and unscrupulous charlatans. This branch of surgery was defined as one which necessitated special knowledge and technical ability, and it was held that the publication of articles was only advisable after the subject-matter had been fully and freely discussed by those experienced and qualified to judge. Without such careful precautions there was danger that a young and fruitful science might be seriously hampered in its healthy development.

In aid of the funds of the college mission at Lambeth, members of Epsom College will present Massinger's *A New Way to Pay Old Debts* at the college on July 19th, and at the Mission Institute in Lambeth Road on July 21st. Tickets (5s., 3s., and 2s.) for either performance may be obtained from the secretary to the Mission Committee, Epsom College, Surrey.

Professor H. G. Greenish, dean of the School of Pharmacy and professor of pharmaceutics in the University of London, is retiring at the end of the present term. He joined the teaching staff of the school in 1890, and was appointed dean in 1914. He was joint editor (with Sir Nestor Tirard) for the 1914 edition of the *British Pharmacopoeia*, and was a member of the Commission responsible for the production of the last (1932) edition. Dr. J. H. Burn, for the past six years director of the pharmacological laboratories of the Pharmaceutical Society, has been appointed dean.

Dr. Pierre Lereboullet, professor of infantile hygiene in the Paris Faculty of Medicine, has been elected an ordinary member of the Académie de Médecine, and Dr. William Mayo of Rochester and Dr. Thorwald Madsen of Copenhagen foreign associate members.

The Secretary of State for Scotland has appointed Dr. A. G. W. Thomson to be a Deputy Commissioner of the General Board of Control for Scotland, vice Dr. G. H. Rae Gibson, deceased.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS *forwarded for publication* are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBER** of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (*Advertisements, etc.*), *Articulate Westcent, London.*
MEDICAL SECRETARY, Mediscera Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Acute Iodism

"H. J. K." writes: The following personal experience of an asthma-like attack following painting of iodine on the skin may, I think, prove of some interest, and I shall be glad to hear of any similar experiences. A short time ago I suffered from an abscess of the forearm (unopened at that time), which was soaked in a hot iodine bath for three-quarters of an hour (strength of iodine, 1 oz. of 2.5 per cent. to half a gallon of water). A few seconds after removing the arm from the bath the area all around the abscess became intensely inflamed and covered with white, raised wheals with red margins (resembling recent flea bites); these gradually subsided during the next half-hour. Three hours later I felt increasing dyspnoea and tightness of the chest, and expiration became very wheezy and difficult. After a time expiratory wheeze became very harsh, and an intense feeling of suffocation was present; a little sticky sputum was expectorated, giving slight relief. The attack subsided after three to four hours. I have never suffered from hay fever or asthma at any other time, but have always noticed some undue sensitivity to iodine.

Alopecia Areata

Dr. J. F. BRISCOE (Newcastle-on-Tyne) writes: I believe, provided the bulbs of the hair are not destroyed, that the application of radiant heat once or twice a week for a short sitting, and then gentle massage may be of use. Castor oil is a good liniment to use with the shampooing. As a tonic I would recommend one of the iron preparations. Butcher's meat should be eaten very sparingly, and a tumbler of warm milk taken night and morning with 1 grain of calomel at bedtime. The bowels must be carefully attended to and alcohol avoided.

"R. M. R." writes in reply to "A. A. H." concerning the treatment of alopecia areata: Here is a prescription I found most successful: Acid. lactic, ʒj to ʒj; ol. ricini, ʒij; spir. vin. rect., ad ʒiv; to be painted on the bald patches once a day. My case was a young man with dark hair. After three months' treatment new growths appeared, at first fair, later dark.

Local Rating

Premises used Professionally

"L." (Essex) owns a house in which two-thirds of the rooms are used for professional purposes. He considers £50 would be a fair rent. Should the figure be increased because of the professional use of the premises?

*** The amount of the gross estimated rental (which forms the gross figure from which the rateable value is derived by the usual deduction for cost of maintenance) should be the amount of the rent which a hypothetical tenant could reasonably be expected to give. If the situation of the property be such that it could command a rent higher than usually given for similar private accommodation because of its business or professional possibilities, then the local authorities may properly take that element into account in estimating the hypothetical tenant's offer.

Income Tax

Life Assurance Allowance

"J. A. W." is being asked to refund an allowance made to him for the year following the maturity of the policy, and has protested that that is unfair seeing that he never received an allowance for the first premium, as the policy was taken out after his return for the first year was made.

*** The allowance is due in respect of payments made in the year of assessment, and, consequently, if the return has been made for the year in which the policy is taken out, a supplementary insurance claim should be made and the policy produced in proof of payment of the premium. As "J. A. W." remarks, that is a point which may not be generally understood. It follows that no allowance is due for the year following the year in which the last premium payment is made.

LETTERS, NOTES, ETC.

Herpes and Varicella

Dr. H. W. HAY (Westerham, Kent) writes: I note with interest Dr. Holloway's case of simultaneous herpes zoster and varicella in which the varicella followed the herpes after seven days (June 10th, p. 1032). Last month I had a case of a man, aged 38, with extensive almost confluent shingles over the right second lumbar sensory area. Three days later the temperature rose and varicella of medium severity developed. Recovery has been normal.

"The Naive and Sardonic Eye"

Dr. HALLIDAY SUTHERLAND (London, W.8) writes: As the subject whose eyesight and insight were thoroughly investigated by the reviewer of *The Arches of the Years* in the *Journal* of June 3rd (p. 965), I would like to thank your reviewer, whose identity is unknown to me, for his most generous criticism both of the book and of myself. In a witty letter, most appropriately written from Paris, Dr. Claude Lillingston takes your reviewer to task in the *Journal* of June 17th for his discovery of "the naive and sardonic eye." Surely Dr. Lillingston has forgotten the "mind's eye," which in all of us is capable of radiating these, and many other, moods—almost simultaneously.

Toby Venner and his "Via Recta"

Dr. F. WILLIAM COCK, F.S.A. (Appledore, Kent), writes: Some time ago I sent you a note on this. On looking again at my copy, Ed: 1650, I find that Thomas Lambards has noted its cost "2' *prim*," that is, price two shillings. I have also obtained Richardson's facsimile of the portrait. This occurs fairly often in printseller's catalogues. The original is distinctly rare.

A Warning

We are informed that a doctor in London placed some outstanding accounts in the hands of a firm of debt collectors whose headquarters were in Edinburgh. Having some doubts about the fidelity of the firm he called at the address in Edinburgh, and found the office closed. He then went to the police headquarters, where he was informed that proceedings were being taken against the proprietors, who had appropriated all the funds they had collected. He identified the photograph of the agent who had canvassed the London district, and was told that this man specialized in obtaining accounts from doctors and dentists.

Autocheques Ltd., 33, Regent Street, S.W.1, have issued a pamphlet describing the services offered by them to those desirous of taking a motoring holiday on the Continent. Books of vouchers are supplied which simplify considerably disbursement for Channel transport, accommodation, meals, tipping, etc., and enable the traveller to estimate beforehand the cost of his holiday. The vouchers are accepted in lieu of cash at hotels (totalling several thousands) in ten European countries. Information is obtainable at the address given above.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 15.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 Chronaxy in Prognosis of Poliomyelitis

PÉHU and G. MORIN (*Journ. de Méd. de Lyon*, March 5th, 1933, p. 137) believe that in infantile poliomyelitis more accurate results can be obtained by chronaxy measurements than by electro-diagnosis. The poliomyelitic virus causes a more or less complete section of and marked alteration in the peripheral motor neuron. The chronaxy is changed in three phases. The initial phase of slight variations lasts only for some days ; at the onset it may be slightly diminished, to fall to a third of its normal value ; it then slowly increases to four or five times its normal. Then it rapidly increases (the phase of rapid augmentation) till at the end of the second or third month 40 to 60 sigmas (forty or fifty times the normal) are registered ; this persists for many weeks. Then follows the phase of diminution ; at the sixth or eighth month the chronaxy diminishes and falls to 10 to 20 sigmas. Though no further change occurs, the excitability of the muscle should be tested by stronger currents at each examination. As the chronaxy varies during several weeks or even months, a single examination is valueless. All the fibres of a normally innervated muscle are isochronous. Owing to various causes the peripheral motor neuron may become totally (by traumatism) or partially (by pathological processes) sectioned. In the former case all the fibres of the muscle become simultaneously degenerated and isochronism persists ; in the latter different fibres of the muscles become unequally degenerated, hence their chronaxy differs and heterochronism occurs. The measures of the chronaxy in seven cases are recorded. A study of these shows that in early cases the prognosis is favourable if, during the first weeks, the chronaxies do not exceed four or five times their normal value. In chronic cases the prognosis is good if the increase of chronaxy is slight. In apparently severe cases a comparison should be made of the chronaxies in the same muscle following excitation either of the nerve or the motor point, or direct longitudinal excitation of the fibres. If the muscle is unresponsive, an evidence of complete degeneration, the prognosis is grave. If in response to these excitations the chronaxies are the same, the prognosis is serious ; if they differ, this heterochronism is a favourable sign as indicating that degeneration is not total and that recuperation can be expected.

2 Aetiology of Thrombo-angiitis Obliterans

In an investigation of two cases of thrombo-angiitis obliterans P. KALLOS and H. NUSSELT (*Klin. Woch.*, March 18th, 1933, p. 425) present evidence in support of the view that this condition is associated with metabolic characters which are referable to sympathicotonia and overaction of the thyroid. The cases ran the typical course leading to ulceration and later to gangrene. In one, amputation of the foot had to be performed, and in the other limitation of the ulceration was attained by " padutin " (a histamine-like substance) and histamine-iontophoresis, but no diminution of the pain could be obtained. Histological study of the amputated foot substantiated the diagnosis of thrombo-angiitis obliterans. The basal metabolic values in these cases were + 8 per cent. and + 26 per cent. respectively, and the specific dynamic action of protein was 20 per cent. and 30 per cent. These figures are indicative of increased rate of metabolic processes, and led the authors to investigate the reaction to adrenaline in these cases. Adrenaline 0.02 mg. was injected intravenously and the blood pressure recorded every fifteen seconds. The curves of blood pressure thus obtained were in both instances higher and more prolonged than those in normal cases, and suggested increased tone in the sympathetic and resembled the curves obtained in hyperthyroidism. Sugar tolerance tests with glucose gave curves which rose steeply and then fell quickly to subnormal values, only reaching normal levels in four and a half hours. Such curves have been found by the authors in hyperthyroidism. The steep rise is regarded as an indication of an overacting thyroid with a secondary oversecretion of the adrenals. The fall below fasting levels is explained as due to the increased avidity of the tissues for glucose, which is then rapidly metabolized. Estimations of potassium, calcium, non-protein nitrogen, uric acid, urea, and bilirubin in the blood gave entirely normal values. No abnormalities in water excretion or urinary constituents could be detected. Having regard to the fact that in the great majority of cases of hyperthyroidism there is a more or less marked constriction of the capillary system, and further that thrombo-angiitis obliterans can be induced in animals by infection with streptococci accompanied by adrenaline injections, the authors consider their findings as strong corroborative evidence that the constitutional basis of this disease is a hyperfunction of the thyroid with a secondary oversecretion of the adrenals.

3 Abdominal Thrombo-angiitis Obliterans

L. A. HULST (*Nederl. Tijdschr. v. Geneesk.*, April 29th, 1933, p. 1886) records the case of a man, aged 36, the subject of thrombo-angiitis in the lower limbs for the last two years, who suddenly developed severe abdominal pain similar to that which he had had in the limbs, and accompanied by vomiting. He had been in the habit of smoking forty to a hundred cigarettes a day. The attack lasted for two days and was little affected by narcotics, but recovery took place in a few weeks. Similar cases of abdominal thrombo-angiitis obliterans in subjects of Buerger's disease have been recorded by Farkas, who found, post mortem, characteristic lesions in the lower end of the abdominal aorta, hypogastric, and common iliac arteries, and by Norpoth, who found similar lesions in the abdominal aorta and mesenteric vessels which had caused multiple intestinal perforations.

Surgery

4 Sclerosing Solutions in Treatment of Cysts and Fistulae

E. C. CUTLER and R. ZOLLINGER (*Amer. Journ. Surg.*, March, 1933, p. 411) strongly commend the use of a modified Carnoy's solution in place of surgical operations for cases of cysts and fistulae. They report that there is less destruction of tissue, much less suffering for the patient, and a quicker convalescence. The solution is composed of 6 c.cm. of absolute alcohol, 3 c.cm. of chloroform, 1 c.cm. of glacial acetic acid, and 1 gram of ferric chloride. It penetrates the tissues moderately, fixing them and the local lining cells, and providing an excellent haemostasis, causing far less reaction than ensues with Zenker's solution or other such agents previously tried. Good results followed in the case of gliomatous cysts in the brain, and also when the treatment was adapted to cervical fistulae and pilonidal sinuses. Clinical details are given in illustration of these claims. The authors add that the cure of fistulae and sinuses along these lines is ambulatory in many cases, there being a considerable saving in expense, both of time and money, through the obviation of a radical surgical operation. Cervical fistulae frequently require a difficult and extensive dissecting process before they can be eradicated by the knife, and a most unsightly scar persists. The sclerosing solution acts more locally and less destructively so far as the adjacent tissues are concerned. The authors were surprised

at the happy results in pilonidal sinuses. After opening the sinus widely, thus allowing the fixative to reach and destroy all the epithelial surfaces, the destroyed lining of the wall was curetted away. Since the patient remains ambulatory and the results were always good, this procedure is worth while trying first, since radical surgery still remains if the success is not fully satisfactory. In neurological surgery it was found that the modified Carnoy's solution penetrated more quickly than other fluids, produced less underlying encephalitis, rendered thin cyst linings tougher and more easily handled, and was a better haemostatic agent. The authors conclude that this solution might well prove to be a valuable adjunct to surgery in the case of a typical suprasellar cyst.

5 Surgical Treatment of Graves's Disease

E. FELDMANN (*Med. Welt*, March 25th, 1933, p. 405) reviews briefly the course of events which have led to the present position in the surgery of Graves's disease, from which, it is suggested, all fear and danger has departed. In Germany the first operations on the thyroid were carried out by Ludwig Rehn in 1884, and it soon became clear that even in the most severe cases extraordinary improvement could be obtained by the method. The danger, however, was post-operative reactions, in which all the manifestations of the disease became accentuated. The mortality from the operation was, up to five or ten years ago, from 10 to 20 per cent. If the first forty-eight hours were safely passed, then recovery was probable, but the position of the surgeon was one of almost entire helplessness in the face of the syndrome. The introduction by Plummer and Boothby of the iodine treatment as a preliminary to operation is regarded by the author as the most important advance in modern times. The authority of Kocher as to the harmful effects of iodine in Graves's disease militated against the early general adoption of the new treatment, but microscopical studies showed that iodine prevents the hyperplasia of the epithelium of the thyroid and so allows storage of the active colloid in the vesicles. The result is that in two or three weeks the improvement in the condition of the patient is so marked that one may at once resect the gland without any fear of later reactions. Attention is drawn to the fact that it is better that the practitioner, after deciding that surgical treatment is necessary, should *not* administer iodine himself, for if he does the surgeon is then more likely to miss that optimum moment at which operation will be best borne. The author believes that the introduction of avertin narcosis has also contributed greatly to a better prognosis. The avertin can be given per rectum without any emotional shock being produced. He points out that these cases require very large doses of avertin, and calls for improvement in the method of administration. The application of these modern methods has lowered the mortality in thyroidectomy to so low a figure—0.5 to 1 per cent. according to American statistics—that the operation may be considered as in no wise dangerous. Of sixty-two cases operated on in the Dantzig City Hospital during the last three years, there was no instance of mortality or failure to improve. The necessity for early operation is stressed, since delay may endanger the heart, kidneys, and other organs.

Therapeutics

6 Radiotherapy in Inflammatory Affections

The general results of early attempts at radiotherapy were so disappointing that its utility appeared to be limited to a small number of cases beyond the aid of surgery or medicine. Recent experiences have, however, shown the value of this treatment in many inflammatory affections. A. PLICHET (*Presse Méd.*, March 4th, 1933, p. 349) summarizes the experience of various authorities who have treated a diversity of acute and chronic infections. In early trachoma rapid improvement followed the employment of radiotherapy, though it proved useless in advanced cases with dense scar formation. Heidenhain and Fried have reported 855 cases comprising boils, erysipelas, anthrax, frontal and maxillary sinusitis, mastitis, orchitis, epididymitis, otitis media, etc., treated with small doses of *x* rays. Of these, 76 per cent. were cured without operation, 19 per cent. were doubtful, while in 5 per cent. the treatment failed; among the latter were included acute osteomyelitis and "cryptogenic" abscesses. Another writer was very successful in the treatment of chronic gonorrhoeal infections—arthritis, prostatitis, salpingo-oöphoritis, etc. In a series of 350 gynaecological cases Wagner found that a single irradiation sufficed in the majority of cases. Treatment was successful in 92 per cent. Two French authors report 78 per cent. of cures in cases of whitlow, anthrax, tuberculous adenitis, tonsillitis, etc. The majority of these patients had had previous vaccine therapy or surgical treatment. In chronic whitlow with undermining of the skin edges ultra-violet irradiation was also employed. Some cases of tuberculous axillary abscess required from four to ten treatments. Duration of exposure should be limited to a few minutes. All authors agree that moderate doses only are required. The earlier failures were due probably to excessive dosage. The dosage recommended is 10 to 20 per cent. of the "erythema dose." Treatment should be given at intervals of three or four days. Apparently the therapeutic action is due to an abundant leucocytosis with bacterial disintegration and antibody formation. Plichet compares the action of *x* rays to that of heat and of the stasis produced by Bier's method, but radiotherapy is superior to these because the dosage and penetration of *x* rays can be regulated exactly.

7 Parathyroid Extract in Gastric Ulcer

J. M. S. RODRÍGUEZ (*Rev. Méd. de Barcelona*, February, 1933, p. 136) records six cases of gastric ulcer in patients aged from 33 to 61, whom he has treated in the course of the last two years by subcutaneous injections of parathyroid extract in doses of 0.5 to 1 c.cm. paratiroidina Byla daily. Care was taken to select only recent cases, without perigastritis or haematemesis. After a few injections the gastric pain and vomiting ceased, and in a few weeks there was a return of appetite, increase of weight, disappearance of nervous depression, and return of normal sleep. The clinical improvement was confirmed by *x*-ray examination, which showed healing of the ulcer. No cases of intolerance were observed.

8 Atropine in Parkinsonism

G. KINBERG (*Nord. Med. Tidskrift*, March 11th, 1933, p. 292) states that in Germany it has been calculated that there are more than 30,000 persons suffering from the effects of lethargic encephalitis. The treatment of these cases has hitherto been very unsatisfactory. Roemer's experience in 104 cases with large doses of atropine is encouraging, as is the author's with six cases. The rationale of this treatment is based on Bremer's observation that the tolerance to atropine in this class of patient is exceptionally great. It tends to increase with the severity of the disease, although in the acute stage atropine has no special action. While, according to Haffner, the ordinary doses of atropine act only on the peripheral nervous system, in large doses the drug acts on those parts of the central nervous system involved in lethargic encephalitis. The dosage begins with 1 drop three times a day of a 0.5 per cent. solution. This dosage is doubled on the second day and trebled on the third. This increase of the dosage by 1 drop is continued until the tenth day, when 10 drops are given three times a day. The dosage is now increased every other day by 1 drop until 20 drops are given thrice daily. It is now increased only every third day until the optimal dosage is reached. Dryness of the throat is no indication to stop raising the dosage, as this symptom usually disappears with a further increase of the drug. If, however, giddiness, palpitation of the heart, and gastric disturbances occur, it may be necessary not to increase the dosage for the next few days. The optimal dosage is reached when there is no further improvement to be noted in the signs and symp-

toms. The dosage is now decreased by 1 drop twice a day until the old symptoms begin to reappear. The process is then reversed and the dosage increased again. This treatment, it is stated, should be carried out in a hospital, and requires on the average three months.

Anaesthetics

9 A Narcotic for Short Operations

K. SPECHT (*Zentralbl. f. Chir.*, February 4th, 1933, p. 242) describes the use of a new preparation for the production of narcosis of short duration, suitable for emergency operations, punctures, incisions, reductions of fractures and dislocations, urological examinations, curetting, and investigations ordinarily involving pain. This substance, sodium evipan, is the sodium salt of *n*-methyl-cyclohexanyl-methyl-malonylurea, and is obtainable in 10 per cent. solution ready for intravenous injection. Experiments on animals have shown it to be without apparent toxic effects. No special preparation of the patient is necessary. The intravenous dose varies according to the age and weight from 0.08 c.cm. for the age of 75 to 0.16 c.cm. for children between 10 and 15 per kilogram body weight; the maximum allowable dose is 10 c.cm. The first 4 c.cm. are injected at the rate of 1 c.cm. in each fifteen seconds and the remainder at 1 c.cm. per ten seconds. The rate of injection is important, as is the case with all intravenous narcotics. Narcosis follows rapidly after the injection and may commence during it. Slight tremors of the muscles are sometimes seen, but never anything approaching convulsions. The narcosis should always be quite light, and lasts, according to the author, for from five to fifteen minutes. In about 33 per cent. of cases the patient falls into a further sleep lasting fifteen to thirty minutes after the period of true narcosis. As in the case of avertin older subjects are, weight for weight, more susceptible than young ones. There are no unpleasant after-effects such as nausea, weakness, headache, etc. If longer unconsciousness is required the narcotic may be used as a method of induction, and the anaesthesia be continued by ether or ethyl chloride.

10 Tetany during Ether Anaesthesia

According to W. N. KEMP (*Anesthesia and Analgesia*, January–February, 1933, p. 1) the occurrence of tetany during ether anaesthesia is not rightly attributable to impurities in the anaesthetic, but to some factor inherent in the patient. He has noticed that those who develop tetany at one operation are liable to do so at subsequent operations. The twitchings of the facial muscles, which are the first sign of this condition, are often followed by an extension of the movements to the muscles of the arms and even of the abdomen. Kemp records a case of perforated gastric ulcer in which tetany commenced only when the abdominal muscles were being stitched after closure of the perforation. On the assumption that the twitching was akin to the tetany of over-ventilation, the patient was allowed to rebreathe oxygen and the expired carbon dioxide, when the condition disappeared. The urine was found to be alkaline, but free from any other abnormality. At a subsequent operation the tetany recurred and was similarly stopped. The author has obtained evidence in support of the view that this condition is due to a temporary alkalosis, caused by the excessive loss of carbon dioxide and the consequent alteration in the blood *p*H. It has been experimentally shown that after twenty minutes of forced breathing a twitching of the facial nerve can be easily induced by tapping the nerve as it crosses the zygoma. Later this twitching may become spontaneous, and in the meantime other symptoms, such as visual impressions and sensations of heat and cold, may supervene, accompanied by a curious fixity of ideas which often makes it difficult to persuade the patient to discontinue the forced breathing. It has been suggested both by Collip and by Grand and Goldman that the condition of alkalosis induced by the forced breathing is the cause of the tetany. Such conditions of forced breathing are duplicated in the administration of ether through an intratracheal tube, especially when oxygen is used as the vehicle to carry the ether vapour. Kemp therefore considers himself justified in concluding that the colonic muscular movements which are sometimes seen in non-epileptic persons under open or intratracheal ether anaesthesia are due to a general alkalosis induced by the rapid elimination of carbon dioxide and the consequent severe upset in the normal respiratory quotient. He discusses the way in which the mechanism operates, and adds that an idiosyncrasy of some kind seems to be concerned.

11 Modern Aids to Anaesthesia

C. F. HADFIELD (*Brit. Journ. Anaesthesia*, January, 1933, p. 62) reviews the modifications in the administration of anaesthetics which have been introduced with the object of rendering anaesthesia safer and pleasanter for patients. Basal anaesthetics, administered by the mouth, rectum, or intravenously, relieve the patient's fears of a general anaesthetic and usually enable the anaesthetist to reduce the dosage of the latter. Administration of the various drugs now employed for this purpose is usually entirely successful. Probably finality has not been reached, nor can any preparation be always equally efficient nor entirely without disturbing sequelae. Rectal administration of paraldehyde is particularly reliable and is safer than avertin. The author states that it is rather surprising that it is not used more generally. Regarding the barbituric acid compounds, Hadfield prefers nembutal—usually in three-grain doses by the mouth for an adult—in ordinary cases. One-third of his patients were unaware of their removal to the operating room; the remainder were usually placid. In almost all cases good muscular relaxation can be obtained with gas and oxygen, combined with far less ether than would be required without nembutal. One of the greatest advantages of avertin and nembutal is the increased susceptibility to nitrous oxide. Hadfield frequently gives one capsule of nembutal overnight and two or three capsules prior to operation, according to the effect of the initial dose. In midwifery sodium amytal is preferable to other barbiturates on account of its prolonged action. Avertin and the barbiturates sometimes produce sleep so prolonged—even after moderate doses—that grave anxiety arises. Some fatalities have occurred. All basal anaesthetics may cause depression of the respiratory centre and post-operative restlessness. Carbon dioxide is invaluable in these cases, and for de-etherization, but a too rapid return to consciousness may subject the patient to much post-operative pain and discomfort.

Obstetrics and Gynaecology

12 Care of Premature Infants

E. NOBEL (*Wien. klin. Woch.*, March 24th, 1933, p. 370) gives a useful summary of the precautions indicated in the care of premature babies. The three principal causes of difficulties in these cases are inadequate heat regulation, feeding difficulties, and liability to infections of the respiratory tract. The insufficiently adapted heat-regulating mechanism becomes manifest through oscillations in temperature from abnormally high to subnormal values, and proper equilibrium is only established after the fourth or fifth week of life. Of the various methods used to correct the tendency to subnormality the author mentions the usual hot-water bottles of different materials, but condemns the use of the incubator-like chambers, since it has been found that the constant inhalation of warm air is undesirable. Modern hospitals are said no longer to use this contrivance. The breathing of fresh air appears to be essential for the normal operation of the respiratory reflexes. He therefore recommends certain types of warm chamber which allow of electrical regulation of body heat, but with the head of the child outside in the fresh

air. The asphyxial convulsions frequently met with in these premature infants can be combated by means of external stimuli such as hot baths, cold douches, and lobeline. Feeding difficulties arise often through failure of the swallowing or sucking reflex, but this is not by any means always the case ; one should always, therefore, give normal suckling a trial. If this fails artificial feeding with a small spoon must be tried, and if this does not evoke the swallowing reflex then a tube must be used via the nose or mouth. The best food is human milk: if an insufficient quantity only can be taken by the child, the milk may be drawn off from the breast and concentrated by the addition of sugar: 100 parts milk and 8.5 grams sugar made up to 150 c.cm. or 100 parts milk and 17 grams sugar made up to 200 c.cm. Long-continued use of such mixtures is not desirable on account of their relatively low protein content. Special attention is drawn to the tendency to sudden respiratory infections in premature infants which hitherto had thriven, these infections being clinically not demonstrable. In many cases such infants are diagnosed simply as debilitas vitae, but post mortem they show unsuspected pneumonic infection. Great care must be taken in the matter of the anaemias occurring in such cases (aplastic anaemias), for which the author recommends 0.3 gram fe. carb. sacchar. Rickets may readily become established in premature infants, so that early special precautions must be taken, such as high-sun radiation, cod-liver oil preparations, or a 10 per cent. emulsion of tribasic calcium phosphate.

13 Induction of Labour by Use of Parturients' Urine

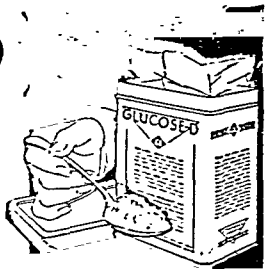
S. S. BARJAKTAROVIC (*Zentralbl. f. Gynäk.*, March 18th, 1933, p. 628) quotes the observations of Guérin-Valmale, Loriot, and Verdeuil, who in two patients ten days before term found that rectal injection of urine from parturient patients was followed in twelve hours by onset of labour pains ; they ascribed this effect to the excretion in the urine of parturients of the excess of labour-determining hormones. Trying a similar method in ten patients, Barjaktarovic found it to fail in the early months, but to be followed by commencement of labour or induction of abortion in six patients who were from five to ten months pregnant ; these included cases of placenta praevia, hydramnios, or post-maturity. Large doses of urine were given, drop by drop, 400 to 500 grams at a time ; usually a daily repetition was necessary, and up to three litres were required Parenteral injections of urine from parturients induced abortion in rats and mice ; injections of ovarian or anterior pituitary hormone were ineffective. The active agent in the urine of labour patients is regarded as a hormone, probably of placental origin.

Pathology

14 Haemagglutination Reaction in Sore Throats (Angina) with Monocytosis

U. FRIEDEMANN and P. BEER (*Deut. med. Woch.*, March 24th, 1933, p. 440) report results which may prove of great interest in the differentiation of various forms of angina as between one another and from other infections. The reaction investigated was that of Hanganatziu and Deicher. The former showed that the serum of patients who had received serum injections for various reasons developed a high degree of agglutinating power for corpuscles of various animals. The reaction appears on the seventh or eighth day after the injection, reaches its maximum on the twelfth or thirteenth, and is still demonstrable after several months. It is independent of the kind of serum used and of the appearance of serum disease. The cells, which can now be agglutinated in high dilutions of serum, may be taken from the calf, sheep, horse, rabbit, guinea-pig, or pig. Isoagglutination titre is not raised. Sheep's cells are either not agglutinated by normal human serum in any dilution, or at most in a dilution of 1 in 4 ; after serum injections the titre rises as high as 1 in 250. For the purposes of the present investigation 1 c.cm. of diluted serum (inactivated at 56° C. for half an hour) is mixed with 1 c.cm. of a 5 per cent. sheep's cell suspension. The dilutions of serum are 1 in 1, 1 in 2, 1 in 4, 1 in 8, etc. The mixtures are allowed to stand twelve hours at room temperature, and the highest dilution at which agglutination takes place is read. A positive finding is recorded if agglutination occurs at dilutions of 1 in 8 or over. As a result of recent clinical experience it has become clear that the differentiation of anginas on the basis of the blood picture only is misleading. In applying the above test to anginas with monocytic reaction in the blood the authors had already the fact that Deicher had found it negative in 200 control cases of various kinds. In nineteen cases of febrile disease with tonsillar exudate and a 50 to 80 per cent. monocytosis (monocytes and lymphocytes), combined with enlargement of lymph glands, spleen, and liver, the reaction was definitely positive, both during the fever and shortly after the temperature had come down. The reaction appears early—in one case on the fourth day—but it disappears earlier than in the case of serum injection. In other diseases with mononuclear reactions—namely, whooping-cough, measles, syphilis (second stage), malaria, agranulocytosis, and lymphatic leukaemia (four cases), the reaction was always negative. Particular emphasis is laid on the fact that it is negative in lymphatic leukaemia. Monocytic reactions in angina are regarded by the authors as including all intermediate cell types from monocytes to lymphocytes ; but only in one case did they find a preponderance of mononuclears as ordinarily defined ; in the others the lymphocytes preponderated. Since some authorities identify monocytic angina with Pfeiffer's glandular fever, the authors investigated a case of the latter which came to their notice and found the above reaction positive (1/32) on the fifth day. In nine typical cases of Vincent's angina the reaction was negative.

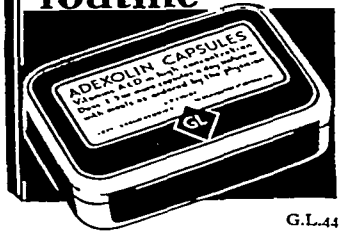
15 Demonstration of "Positive Sputum" by Guinea-pig Inoculation



A. FARJOT (*C. R. Soc. de Biol.*, March 17th, 1933, p. 987), regarding the guinea-pig method of inoculation as the surest means of demonstrating tubercle bacilli in sputum, has endeavoured to ascertain the most suitable procedure for preparing the sputum for inoculation. Three methods were tried: (*a*) injection of 2 c.cm. of untreated sputum ; (*b*) injection of 2 c.cm. of sputum which had been left in contact with an equal volume of 4 per cent. caustic soda solution for half an hour at 37° C. and then neutralized with 33 per cent. acetic acid in the presence of neutral red ; and (*c*) injection of sputum homogenized by Petragnani's method—digestion of one part of sputum with four parts of 3 per cent. caustic soda solution for forty-five to sixty minutes at 37° C., followed by centrifugation and neutralization of the deposit with 4 per cent. HCl in the presence of litmus. Since necessity of economizing in animals prevented the inoculation of three guinea-pigs with the same sputum treated by the three methods, each specimen was treated by only one method and inoculated into a guinea-pig, reliance being placed on the examination of a sufficiently large number of animals to obtain comparative results. Using the first method, 318 guinea-pigs were inoculated ; fifty (15.7 per cent.) died prematurely, and of the remainder fifty-two became tuberculous—that is, tubercle bacilli were demonstrated in 16.4 per cent. of the total number. Sputum treated by the second method was injected into 780 guinea-pigs ; of these, forty-six (5.9 per cent.) died prematurely, and of the remainder eighty-two (10.5 per cent. of the total number) became tuberculous. Sputum treated by the third method was injected into 367 guinea-pigs ; of these, seven (2 per cent.) died prematurely, and of the remainder thirty-six (9.8 per cent. of the total number) developed tuberculosis. It appears, therefore, that though preliminary treatment with soda diminishes the number of premature deaths caused by contaminating organisms, the highest total percentage of positive results is obtained by the use of untreated sputum.

The *debilitated* patient and the athlete

Even these extremes meet in their need for: (a) immediately accessible energy, i.e., glucose; (b) elements to nourish and control their nerve cells and reflexes, i.e., calcium and phosphorus; (c) vitamin D to ensure the assimilation of these elements.



Glucose-D is richly supplied with all these components. Whenever glucose is prescribed—whether as a therapeutic agent or as a product for everyday use, as a remedy for acidosis or a source of nourishment in fevers, as additional energy during periods of physical and mental strain or a "nutrient tonic" for debilitated adults and children—Glucose-D, the reinforced calcium vitamin glucose, is the preparation of choice. 1 lb. tins—1/9 7 lb. tins—10/6

GLUCOSE-D

GLAXO LABORATORIES, 56 OSNABURGH STREET, LONDON, N.W.1

In ante-natal routine

Could any ante-natal routine be more definite—or simpler?

The expectant mother—following a procedure in force in leading hospitals and ante-natal centres—takes one capsule of Adexolin a day during the last 100 days of her pregnancy. In this way she takes every day a precisely measured amount of vitamins A and D in natural proportions.

The vitamin A of Adexolin serves to protect the mother against puerperal fever and to fortify the resistance of the foetus to neo-natal and infantile infections.

Adding the calcium-regulating vitamin D helps to preserve her teeth from decay and to promote normal skeletal development in the unborn infant.

Each 3 m. capsule of Adexolin contains 20,000 units of vitamin A and 1,000 international units of vitamin D. The protective and mineralizing effect of both vitamins can be secured with certainty by giving one Adexolin capsule a day during the last three months before confinement.

Boxes of 100, 8/6. Also in tins of 500 & 1,000.

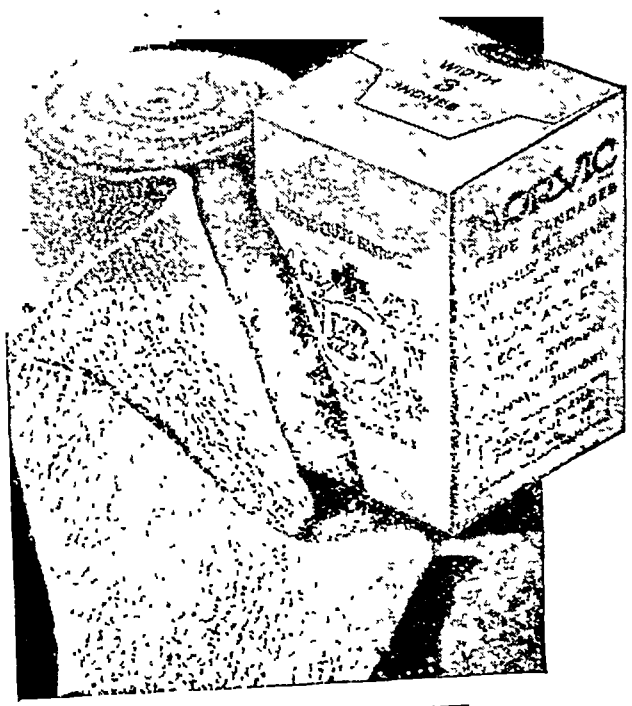
VARIBAN

ELASTIC PLASTER BANDAGE



The use of "VARIBAN" Elastic Plaster Bandages makes for the successful treatment and the speedier recovery of the patient suffering from Varicose Ulcers, Varicose Veins, Strains, or Fractures. These Bandages, evenly spread with an Antiseptic Zinc Oxide Paste, readily conform to the shape of the limb and provide the firmest support, and yet permit of easy removal. The most modern treatment yielding the most satisfactory results. Supplied in four widths: 2", 2½", 3" and 4", at 1/9, 2/-, 2/3 and 2/8 each, respectively. Sample 3" bandage sent on receipt of P.O. for 2/6, in order that you may judge "VARIBAN" Bandage in your own practice. Write direct to the manufacturers.

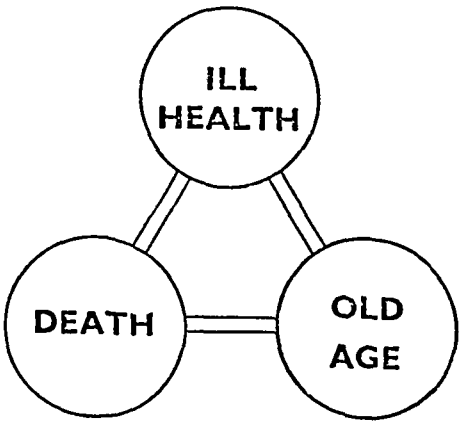
SURGICAL SERVICE SALTAIR

SALTAIR SURGICAL SERVICE

..LIGHTER FOR SUMMER BUT JUST AS EFFICIENT

Summer weather which calls for a general lightening of apparel is equally insistent upon lighter appliances. And yet the same degree of corrective support is quite as essential. In Salt's specially light Summer Appliances greater freedom and ease, due to reduced weight, is combined with equal efficiency as in the ordinary types. The desirability of lighter appliances for Summer is not only obvious on hygienic grounds but there is much to be said for the fact that the possession of two appliances enables the Winter type to be returned for necessary cleaning and rehabilitation . . . which is economy in the truest sense. Catalogues of all appliances will be sent to Medical Men on request with time-saving measure and order forms.



Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Ki-uma Brand

OINTMENT for RHEUMATISM

This ointment is a clinical and physical combination of:

Ol. Bassiae Parkii.
Salicylic Ester Dihydroxethane (90% Salicylic Acid content). Ol. Eucalypti glob.

Reports received from Private Practitioners show that this Ointment does possess therapeutic properties of a high order. It is proving itself to be one of the best applications for treating Rheumatic disorders.

Clinical Sample and Literature on request.

The Managing Director, KI-UMA LTD., Circus Place, BATH.

B. ACIDOPHILUS INTESTINALIS.

Live cultures are now supplied either as (a) broth cultures in bottles, or (b) concentrated emulsion in ampoules.

(a) In bottle is more suitable for the milk method of administration.

(b) In ampoule for the fruit-juice method.

Both are probably equally efficacious as remedies for intestinal putrefaction, indicanuria, chronic constipation, etc.

PRICES:

In bottle (returnable) ... ... 6/- each
In ampoule (one dose) ... 1/- each

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, *with special nurses, male or female, in the Hospital or in one of the numerous villas* in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special department[illegible] methods, including Turkish and Russian baths, the prolonged imme[illegible] Douche, *Electrical bath, Plombières treatment*, etc. *There is an* [illegible] *Surgery, an* X-ray room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given *every facility for occupying themselves* in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, *such as carpentry, etc.*

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180–1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this unit is found the X-Ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms, and Occupational Therapy under competent instruction is encouraged.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician Superintendent at the Hospital.

14 DAYS' TOUR TO BUDAPEST

23 Guineas

Including a stay at BALE, VIENNA, INNSBRUCK and PARIS.
NO NIGHT TRAVEL.

Itinerary

1st day—To Bale. Night at Hotel.
2nd day—To Vienna. **Official reception by Austrian Government and City of Vienna.**
3rd day—Vienna, with excursion.
4th day—Vienna, excursion to Wiener Wald.
5th day—To Budapest by Danube steamer. **Official reception by Hungarian Government.**
6th day—Budapest. Evening concert.
7th day—Budapest, excursion to Hills of Buda.
8th day—Budapest, excursion to Siofok on Balaton Lake (the largest in Europe). Evening concert.
9th day—Budapest. At leisure.
10th day—To Innsbruck.
11th day—Innsbruck. At leisure.
12th day—To Paris.
13th day—Paris. At leisure.
14th day—To London.

Doctors taking this tour will be received by the Hungarian Medical Authorities at Budapest, and special facilities will be arranged for visiting the thermal establishments.

DEPARTURES FROM LONDON, SATURDAYS, JULY 29, AUG. 19, SEPT. 16

These three departures for a 14 days' inclusive tour to Budapest have been organised by special arrangement and have the official support of the **Hungarian** and **Austrian Governments.**

It is due to a system of international exchange trains which is being arranged for the first time between England and Hungary that such a magnificent opportunity is offered for an inclusive visit at a minimum of expense.

When it is realised that an ordinary 2nd class return ticket to Budapest costs nearly £23, then it can be seen at once what phenomenal value is being offered by studying the itinerary and the various items which are being provided at an inclusive sum of 23 guineas.

The charge for the tour is fully inclusive and provides for: travel tickets from London and return, 3rd class England and 2nd class Continent; full accommodation at first class hotels; gratuities at hotels and local taxes; excursions with English speaking guides; transfers; meals en route. Representatives will accompany the party throughout.

Apply for Special Programme to

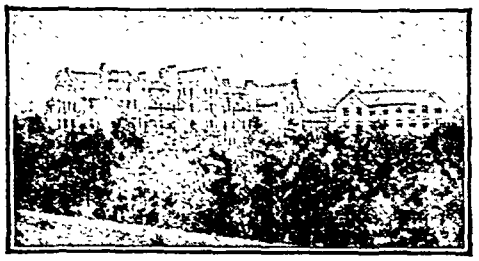
HARROGATE

for the Treatment of GOUT, RHEUMATISM, ARTHRITIS, FIBROSITIS, NEURITIS, ARTERIO-SCLEROSIS and HYPERPIESIS, Diseases of the LIVER and GALL BLADDER, GASTRIC CATARRH and COLITIS, SKIN DISEASES, ANAEMIA, and Convalescence from Acute Illness.

SULPHUR, Saline Iron and Pure Chalybeate waters, together with the presence of large deposits of Volcanic Mud, enable Harrogate to offer every facility for the cure of an unusually wide range of the diseases amenable to Spa Treatment.



The Harrogate Royal Baths, housed in one of the finest Spa buildings in Europe, are equipped with the most modern apparatus for all forms of Physiotherapy.

THE "CURE" is taken in a holiday environment: three golf courses, putting greens, hard tennis court, swimming baths, beautiful gardens and moorlands encourage sport and exercise. First-class hotels, hydros, boarding houses and private apartments meet all requirements for accommodation.

Harrogate is an ideal holiday centre and is surrounded by some of the most beautiful scenery in England.

Members of the Medical Profession are asked to write for particulars of Complimentary Facilities to:—
F. J. C. BROOME,
General Manager, 3, The Royal Baths, Harrogate.

WORCESTERSHIRE COUNTY COUNCIL.

ASSISTANT MALE COUNTY MEDICAL OFFICER.

The above mentioned Council are about to appoint a Male Assistant County Medical Officer, and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45 and preference will be given to the possessor of the D.P.H.

The duties will include those connected with the School Medical Service and the County Maternity and Child Welfare Scheme, together with any other health duties the Council may require.

The officer appointed will work under the supervision of the County Medical Officer, and will be required to reside in the district assigned to him by the County Council, and to devote the whole of his time to the work.

The salary will be £500 per annum (less a temporary economy deduction of £21 10s.) rising by annual increments of £25 to £700 per annum, with an allowance of £140 per annum for use of own motor car.

The post is designated under the Local Government and Other Officers Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

The engagement will be subject to three months' notice on either side.

Applications (on forms to be obtained from the County Medical Officer, County Buildings, Worcester), accompanied by not more than three recent testimonials, must be received by 12 noon on Saturday July 15th, addressed to the County Medical Officer, County Buildings, Worcester.

Canvassing disqualifies, and neither the names of the members of the County Council, nor of the Committee will be supplied.

Shirehall, Worcester. (Signed) C. H. BIRD, Clerk of the County Council.
June 26th, 1933. (B.218.)

PORT OF CARDIFF.

RESIDENT MEDICAL OFFICER.

The Royal Hamadryad Seamen's Hospital invites applications from registered Medical Practitioners (male) for the whole-time appointment of Resident Medical Officer to the Hospital which consists of 70 beds and Out-patient Department with a V.D. Clinic.

Candidates must possess the certificate in Venereal Diseases prescribed by the Public Health Qualifications of Officers Regulations, 1930, and if possible have had further experience in that work. Consideration will be given to the possession of experience of administration.

The appointment will be limited to a period of three years with the option of renewal if desired by both parties.

Salary £600 to £650 per annum by annual increments of £25, with unfurnished residence, free from rates and taxes, adjacent to the Hospital, or in the case of an unmarried man, board, lodgings, laundry, and services, in either case valued at £135 per annum.

[illegible] September 1st.

[illegible], whether married or [illegible] previous medical, V.D., surgical, and administrative experience, and present occupation must be sent to the undersigned not later than July 14th.

Some experience of port work would be regarded as an additional qualification.

A print of the terms of appointment can be obtained from me.

CITY OF NOTTINGHAM.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Assistant Medical Officer of Health (male) to commence duty on October 1st.

The duties will include assisting the Medical Officer of Health in the administration of the Maternity and Child Welfare Department, taking medical charge of certain Infant Welfare sessions, undertaking medical duties of a non-specialist type at the Tuberculosis Clinic, together with such other duties as may from time to time be allotted.

The possession of a Diploma in Public Health is essential.

Service with other Local Authorities will be taken into consideration in fixing the commencing salary, which will be on the scale £500, rising by annual increments to £700.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to one month's notice on either side.

The successful candidate will be required to live within the City Boundary and to pass a medical examination.

Applications must be made on a form to be obtained from me and must be addressed so as to reach me not later than July 15th.

Guildhall, W. J. BOARD,
Nottingham. Town Clerk.
June 19th, 1933.

SURREY COUNTY COUNCIL.

SCHOOL DENTAL SURGEON.

Applications are invited from qualified registered Dental Surgeons, preferably under 35 years of age, for whole-time dental work in the County.

The officer appointed will be required to act under the supervision and control of the County Medical Officer, and to live at some centre to be approved by the Council.

Commencing salary £500 per annum, rising by increments of £20 for each year of approved service to £600 per annum, but subject to a reduction of 5 per cent. on the amount in excess of £150 until October 31st.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Form of application, together with further particulars, may be obtained from the County Medical Officer, County Hall, Kingston-upon-Thames, and must be returned duly completed, not later than Friday, July 7th.

Communications must be endorsed "School Dental Surgeon." Canvassing will disqualify.

County Hall, DUDLEY AUKLAND,
Kingston-upon-Thames. Clerk of the
June 16th, 1933. Council.

APPOINTMENTS.—Contd.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL,
Gray's Inn Road, W.C.1

RESIDENT HOUSE SURGEON (MALE).

There will be a vacancy for a Third Resident House Surgeon to enter on duty on September 1st next.

The appointment will be for a period of nine months, three months as *Third House Surgeon*, three months as Second House Surgeon, and three months as First House Surgeon. Remuneration at the rate of £75 per annum.

Applications, accompanied by copies of not more than three testimonials, should be sent to the undersigned on or before July 10th.

JOHN H. YOUNG, Secretary-Supt.

WEST LONDON HOSPITAL, *Hammersmith, W.6.* (234 Beds)

Applications are invited for the post of HONORARY MEDICAL REGISTRAR to the Children's Department, for a period of one year, eligible for re-election annually for a total period of not more than three years. An honorarium at the rate of £100 a year is attached to the post

The duties include attendance in the Out-patient Department on four mornings a week, acting as deputy for the Assistant Physician to the Children's Department when required and such teaching for the Post-graduate College as the Board may approve.

Candidates, who may be male or female, must be registered under the Medical Act, and should have had wide experience in Children's work. Membership of one of the Royal Colleges of Physicians of London, Edinburgh, or Ireland is desirable

Applications, with copies only of testimonials, should reach me not later than Thursday, July 20th. Candidates must attend the Meeting of the Medical Council at 4.30 p.m. on Friday, July 21st, and prior to that date send copies of application and testimonials to each member thereof. They must not canvass members of the Board but, nevertheless, should send copies of their applications and testimonials to each member thereof, and if so notified, be in attendance at a Meeting of the Board at 5.15 p.m. on Tuesday, July 25th, when the election will be made

H. V. MADGE, Secretary.

YORK DISPENSARY.

Applications are invited for the post of RESIDENT MEDICAL OFFICER (Female) to commence duties as soon as possible.

The Directors expect the post to be held for not less than one year though this is not a condition precedent to the appointment

The resident staff consists of two medical officers, whose duties are to visit and attend the sick poor in their own homes, and to assist the honorary staff. Some experience of the administration of anaesthetics is essential. Salary £175 per annum, with board, lodging, and attendance, and allowance for laundry. Applications with testimonials, to be sent on or before July 8th, to—

4, New Street, York. JOHN C. PETERS, Secretary.

KENT COUNTY MENTAL HOSPITAL, *MAIDSTONE*

ASSISTANT MEDICAL OFFICER (Male) required. Commencing salary, inclusive of emoluments, £509 per annum, rising to £659 per annum. Excellent facilities for attending lectures for the Diploma in Psychological Medicine, and an additional £50 per annum for that Diploma

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, LESQUARE-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD-HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50). Full Schedule of Terms and Conditions will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. HOME COUNTIES.—PARTNERSHIP.—A one-third share (with increase up to one-half later) is offered, owing to the retirement of the senior partner, in an old-established good mixed Practice, situated in favourite residential town within easy reach of London. Gross cash receipts average approximately £4,000 p.a. Panel of 3,200. Visits and medicine from 4/-. Suitable house, with garden and garage, can be rented at £70 p.a. Sport of all kinds, and good schools. Ingoing partner must be about 30 years of age, married or engaged, and experienced in major surgery, and pref. hold the F.R.C.S. Premium for share, two years' purchase.
2. KENT.—WITHIN TWENTY-FIVE MILES OF LONDON.—PARTNERSHIP.—A one-third share (with increase to one-half later) is offered in an old-established good mixed-class Practice, with a large percentage of good-class patients, and situated in a very attractive country and market town (pop. over 3,000) amidst beautiful surroundings. The income is steadily increasing, and there is good scope for further development with the aid of a suitable partner, who should be about 30 years of age. Cash receipts last year nearly £2,400. Visits 3/6 to 21/-, medicine extra. Choice of suitable houses ranging from £1,000 upwards. Premium for share £1,600. Sport of all kinds. Good schools.
3. WITHIN FIFTEEN MILES OF LONDON.—PARTNERSHIP.—A share producing about £1,300 p.a. is offered in a very sound old-established Practice, producing for the last 12 months approximately £5,200, and offering excellent scope for increase. Panel of 2,500. Fees from 3/6 to 21/-. Very nice house, with ample accommodation, or smaller one if desired. Ingoing Partner should be experienced, accustomed to better-class work, able to undertake major surgery, and pref. hold a Fellowship. Premium 2 years' purchase.
4. PARTNERSHIP.—LONDON SUBURB.—A one-third share (with increase up to one-half later) is offered in a very old-established good mixed-class Practice, situated in well-populated district, and offering good scope for development. Gross cash receipts average between £4,000 and £4,500 p.a. Guaranteed income of £1,500 for the first year. Panel of 800. Suitable accommodation available. Premium for share £3,250. Ingoing partner must be experienced, and qualified about four years.
5. CORNISH RIVIERA.—Old-established PRACTICE, in very favourite resort, having exceptionally mild climate. Income over £1,150, including panel of 450, and appts. worth £40 p.a. Fees 3/6 to 21/-. No opposition within 4 miles. Well-situated house, with 2 reception, 6 bedrooms, etc., and professional rooms. Good garden. Rent on lease £52 p.a. Premium £1,650.
6. NORTH OF ENGLAND.—PARTNERSHIP.—A five-twelfths or seven-twelfths share is offered in a well-established sound mixed-class Practice, averaging approximately £2,400 p.a. Panel produces £850 p.a. and P.M.S. £720 p.a. Appointments worth £120 p.a. Succession to the whole Practice can be obtained in about four years, or sooner as agreed. Good house, specially built, with ample accommodation, for sale. Situated in growing area, and offering excellent scope for further development. Premium for share 2 years' purchase.
7. EASTERN COUNTIES.—Very old-established PRACTICE, unopposed, and situated in pleasant agricultural district, within reach of two good towns. Average gross cash receipts for the last three years £1,849 (last year £2,237). Panel with mileage produces over £900 p.a., and appts. are worth about £130. Fees from 3/6. Comfortable house, with 2 reception 6 bedrooms, etc. Garden. Garage. Price (freehold) £1,500. Premium £3,200.
8. LONDON SUBURB (EAST).—In a clean and well-populated district an old-established PRACTICE worth about £1,200 p.a., including transferable appt. of £150 and panel of 950 is for immediate disposal, owing to ill-health of Vendor. Small house (3 bedrooms, etc.), with fair-sized garden. Rent on lease £78 a year, inclusive of rates and taxes. Premium 2 years' purchase.
9. LIVERPOOL. — Old-established PRACTICE, averaging £1,046 p.a. including panel of about 1,500. Fees from 2/6. Midwifery refused. Eight-roomed house, with professional accommodation, electric light. Small garden. Price £500. Premium 1½ years' purchase.
10. PARTNERSHIP.—RIVERSIDE SUBURB (WEST).—A fourth Partner (who should be married and about 35 years of age) is required in a very old-established mixed-class Practice, situated in pleasant residential suburb. Cash receipts for past three years average £6,879 p.a. A three-twentieths share is offered, with option in four years to increase up to equal shares with the other Partners. Appts. held and panel of about 3,000. Visits 3/6 to 21/-. Modern house, with good accommodation (5 bedrooms, garden). Price (freehold) £2,000, or would be let at £125 p.a. Premium 2 years' purchase.
11. WITHIN THIRTY-FIVE MILES OF LONDON.—Very old-established country PRACTICE, in pleasant residential district. Gross cash receipts for the last twelve months approximately £1,800. Panel brings in over £650 p.a. and appts. are worth nearly £200 p.a. Fees from 2/6 to 15/-. Midwifery 3 to 10 gns. Nice house in one acre of garden and 2 acres of orchard, and containing 3 reception, 6 bedrooms, etc., and professional rooms. Electric light. Main drainage. Garage. Price for freehold £2,500, £1,000 on mortgage. Golf, tennis, and other sport. Premium £2,500.
12. LONDON, WEST.—PARTNERSHIP.—A half share, producing about £750 p.a. (which will be guaranteed for the first year) is offered in a very old-established better-class non-panel and non-dispensing Practice, having exceptional scope for increase. Fees from 10/6 to 5 guineas. Suitable Flat is available for ingoing Partner who must be experienced in better-class work, and preferably hold the M.R.C.P. Premium for share 2 years' purchase.
13. SOUTH WALES.—Pleasant Coast Town (pop. 40,000).—Old-established PRACTICE, held ten years by present Incumbent, and averaging over £1,000 p.a., including panel of 1,275. Visits 5/- to 10/6. Good house, having charming views of English Channel, and surrounding country. Contains professional rooms, 3 reception, 6 bedrooms, 2 bathrooms. Garden, with tennis court. Garage. Price for leasehold (60 years to run at ground rent of £20 a year) £1,800. Premium 1½ years' purchase.
14. LONDON, S.W.—Well-established PRACTICE, worth about £350 p.a. including panel of 550, and capable of increase. Rent of Flat, consisting of two floors, containing 2 professional rooms, dining room, kitchen, two other rooms and bathroom, £2 2s. a week, inclusive of rates and taxes. Lease 5 years to run, and renewable. Premium £450, or near offer.
15. EASTERN COUNTIES.—ASSISTANTSHIP with view to Partnership (after a preliminary period of six months at a salary of £440 p.a., with free house) is offered in an old-established good mixed-class Practice, situated in pleasant residential and agricultural district within about 15 miles of the coast. Gross cash receipts approximately £3,000. A third share is for disposal at a premium of 2 years' purch.
16. NORTH WALES.—ASSISTANTSHIP with view to Partnership (after a preliminary period of about six months at a salary of £300 p.a., all found) is offered in a better-class non-panel Practice, situated in attractive seaside resort. A one-third or three-sevenths share is for disposal (producing £800 to £900 p.a.) at a premium of 2 years' purch. Ingoing Partner should be English, and pref. London trained.
17. PARTNERSHIP. — WEST OF ENGLAND, SEASIDE RESORT. — A share worth about £600 p.a. (with succession to the whole Practice eventually) is offered in a very old-established mixed-class Practice situated in very attractive small coast town, with beautiful surrounding country. Gross cash receipts approximately £1,200 p.a., including panel worth about £420. Visits 5/- to 30/-. Midwifery from 3 gns. Exceptionally nice house, with 2 reception, 5 bedrooms, etc., and usual offices. Half an acre of garden. Can be rented on lease. Premium 2 years' purchase.
18. RIVERSIDE SUBURB.—Middle and working-class PRACTICE, averaging £1,033 p.a., including panel producing about £340, and appts. nearly £100 p.a. Fees from 3/6. Detached house, with nice garden, and containing 4 reception, 6 bedrooms, etc., for sale. Premium 2 years' purchase.
19. OPHTHALMIC PRACTICE.—Within eighty miles of London.—Practice is increasing, and offers good scope for further development. Average gross cash receipts for the past three years £554. Last year over £700. Fees 1 to 2 guineas. Opposition slight. Choice of houses. Premium £700.
20. LONDON, EAST.—Middle and working-class PRACTICE, producing £1,000 p.a., including panel of about 1,100. Suitable small house with sitting room, 2 bedrooms, and attic, waiting room, surgery, and dispensary. Rent £52 p.a.
21. LONDON, SOUTH-EAST.—Old-established better working-class PRACTICE, increasing, and situated in well-populated district. Gross cash receipts for last 12 months £1,263, including panel of 1,370. Suitable house, with 2 reception and 3 bedrooms. Garden. Price for freehold £1,000. Premium £2,500.
22. MANCHESTER.—Old-established middle and working-class PRACTICE, producing for the last twelve months about £650, including panel of 790. Fees from 3/6. Convenient house, with 2 reception, 4 to 5 bedrooms, bathroom, etc. Rent on lease £60. Premium £950, to include furniture.
23. SOUTH-EAST LONDON.—Good middle and working-class PRACTICE, producing last twelve months nearly £950. Panel of 986. Suitable house, with 2 reception, 4 to 5 bedrooms, etc. Rent on lease £70 p.a. Prem., to include drugs, etc., and surgery fittings and furn., £1,450.
24. CENTRAL LONDON.—Middle and better-class PRACTICE, averaging for the last two years about £500 p.a., including small panel of 180. Fees 3/6 to 21/-. Professional accommodation can be rented at £200 p.a. Prem. £300, to include furn., drugs, instruments, etc.
25. SOUTH-WEST OF ENGLAND.—In a thriving and pleasant seaport town, with beautiful surrounding country, a well-established increasing PRACTICE worth last year over £1,100, including panel producing £286 and appts. £200. Visits 3/6 to 21/-. Midwifery practically refused. Good house in excellent position, with ample accommodation, small garden, and garage. Price, freehold, £2,100 or would be let on lease at £127 p.a. Premium £2,000, or near offer.

ASSISTANTS REQUIRED.—(1) BUCKS. Better-class Practice. Indoor £300 p.a., or outdoor by arrangement. (2) YORKS. Outdoor £400 p.a., with free house. Must be English and married. (3) SOUTH WALES. Indoor £300 p.a. Must be young, and able to drive car.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

For difficult Infant Feeding Cases

The difficulties and trouble of predigesting and peptonising milk for the use of invalids and others suffering from gastric weakness are now overcome by this highly scientific preparation. Peptalac is a dry stable powder. The simple addition of hot water yields a predigested and peptonised Full Cream Milk. Peptalac is not only invaluable to invalids, but, containing as it does a proportion of predigested wheat flour, it will serve as an ideal food to wean infants taking more solid foods at 8—9 months.

PEPTALAC

Brestol is an emulsion of 50% Fats, 40% Dextrose and contains biologically tested cod liver oil and orange juice. It is indicated in all cases where an increase of weight is desired, and for all forms of milk modification.

BRESTOL

This is a lactic acid milk in powder form, made in three strengths, namely Lacidac Separated (1% Fat), Lacidac Half Cream (16% Fat), and Lacidac Full Cream (27% Fat). It is proving of great value in the feeding of infants recovering from gastro-enteritis, broncho-pneumonia, and other diseases, and eliminates the difficulties and disadvantages of administering liquid milk treated with lactic acid, as proposed by Marriott.

LACIDAC

This was prepared originally for the special requirements of a well-known pediatrician for the feeding of premature and frail infants. It contains a large percentage of easily assimilated sugar, a condition which is very necessary in the feeding of these infants. The successful application of Frailac has prompted us to widen its utility amongst the medical profession. Frailac is not intended as a permanent food but on normality being reached our Half Cream Cow & Gate is specially recommended.

FRAILAC

This is a Full Cream Milk to which has been added Iron Ammonium Citrate B.P. and subsequently powdered by the Cow & Gate Improved Roller Process. It was the food used exclusively in the now famous investigations by Dr. H. M. M. Mackay on Nutritional Anæmia in Infancy (Medical Research Council Report, Special Series: No. 157). Hemolac is indicated in the Nutritional Anæmia of infancy, and for premature infants.

HEMOLAC

These Foods are indicated for all cases of fat intolerance such as is indicated in cœliac disease and gastro-intestinal disorders. They are both standardised Cow & Gate preparations. Attention is also drawn to the fact that the Special Half Cream Food (containing no extra lactose) is still available.

SEPARATED & HALF CREAM

This has been prepared at the request of a leading London Hospital for the treatment of allergy in infancy. It is characterised by the fact that its protein is denatured, that it is practically free from lactalbumen, and that its pH value has been suitably modified.

ALLERGILAC

Caprolac is goat's milk modified by the addition of lactose and the partial elimination of fat, and then powdered by the Cow & Gate Improved Roller Process. Like goat's milk this has been recommended for the treatment of eczema in infancy. It is a standardised powder and like all our other products can be relied upon for bacteriological sterility and safety.

CAPROLAC

COW & GATE LTD. GUILDFORD, SURREY

Clinical samples and literature will be gladly sent on request to any member of the Medical Profession.

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
2 c.c. size: Boxes of 10 ampoules.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—
Chocolate Flavoured (25 grains). Boxes of 30 and 150. Cartons of 12 boxes of 30.
Effervescent (60 grains). Tins of 12 and 66.

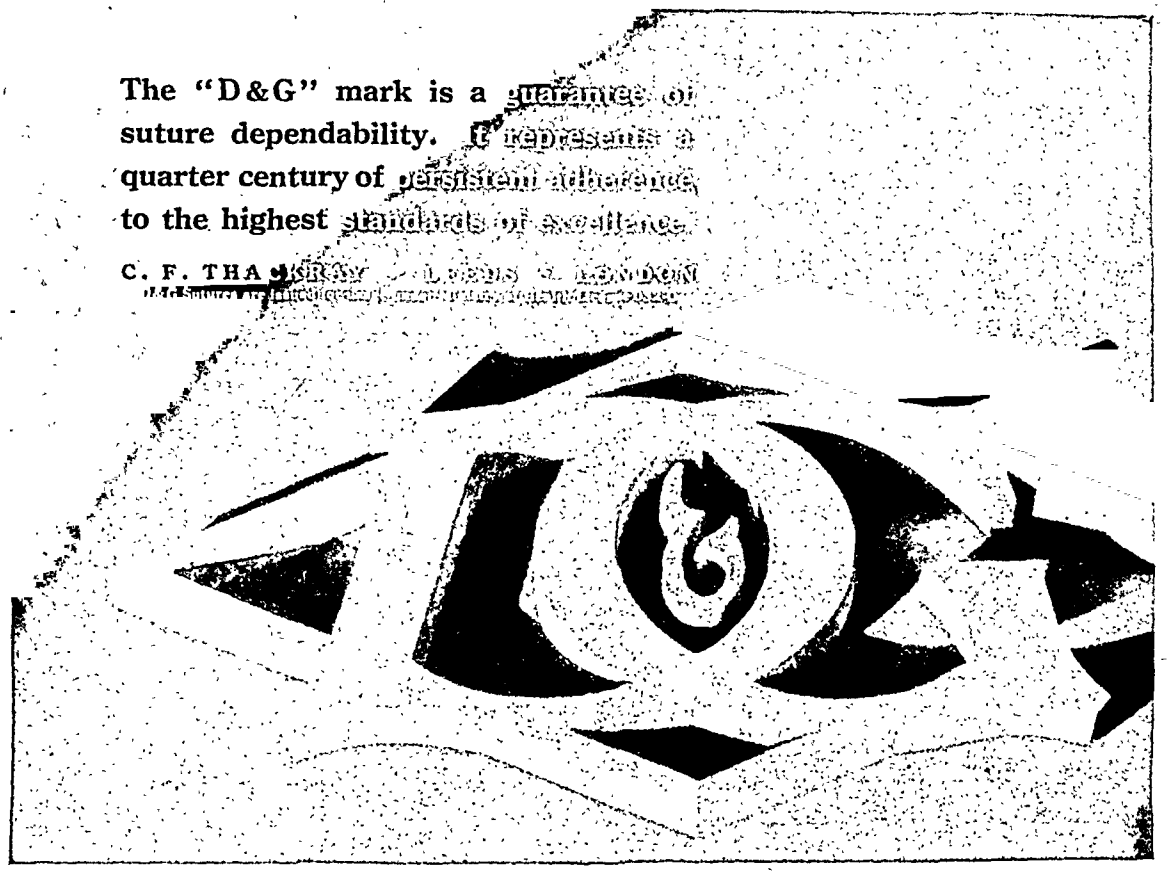
The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.



Descriptive literature and a clinical trial sample will be sent on application.

Full particulars and forms of application for membership can be obtained from the Secretary, 49, Bedford Square, W.C.1.

Notes on the Advertising facilities offered by the B.M.J.

The British Medical Journal is open to accept advertisements for any approved products or services appealing to the professional and private needs of the *medical profession*. A large section at the rear of the Journal is devoted to "domestic" announcements regarding Practices wanted and for sale, Partnerships, and Assistancies, also Hospital Vacancies and Miscellaneous advertisements.

All communications and enquiries referring to advertisements should be directed to

STUDIES ON THE PHYSIOLOGY OF THE EYE

STILL REACTION, SLEEP, DREAMS, HIBERNATION, REPRESSION, HYPNOSIS, NARCOSIS, COMA, AND ALLIED CONDITIONS

By J. GRANDSON BYRNE

*** This volume is the outcome of twenty years of work in various laboratories in England, Europe, and America. A few of the Studies were published in scientific journals, but other activities, as well as continuous research, left no time for the preparation of separate portions for publication. The present volume of 440 pages and the arrangement of the chapters is the result of these circumstances. It is a unique record of close observation and careful analysis of results.

DEPENDABLE

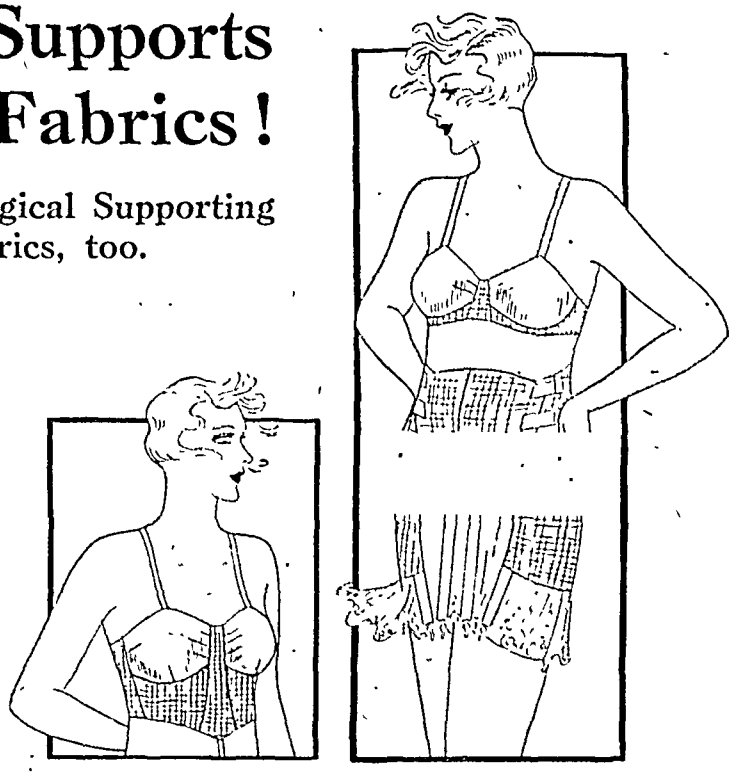
The reputation of the House of Curtis stands high. Over 3,000 doctors and surgeons are sending their patients to us or obtaining our appliances for them. You may do likewise with perfect assurance of scientific treatment, correct attention to details, intelligent interpretation of your instructions and strict compliance with ethical rules.

Every practitioner should be in possession of the Curtis Book of appliances giving full information, measurement forms and prices of a wide range of articles in the following groups:

Abdominal Supports	Abdominal Belts
Special Corsets	Trusses
Colostomy Appliances	Elastic Hosiery

If you have not received a copy of the latest edition may we have the pleasure of sending one to you? Please remember that we have been established for 30 years and have justly earned the reputation of being specialists in the field of abdominal support.

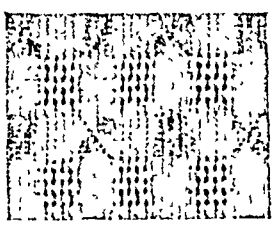
H. E. CURTIS & SON LTD.



Sole Manufacturers of the "Curtis" Appliances.

7, Mandeville Place, Wigmore Street, LONDON, W.1.

Telephone: WELBECK 2921.



Cool Maternity Supports of Open, Airy Fabrics!

"Uplift" Bandeaux, Belts and Surgical Supporting Garments of Summer Fabrics, too.

Below is an actual photograph of the *material* of which Spencer *Summer* Maternity Supports and other surgical garments can be made. Supports of this fabric are light as a feather, cool and airy, designed to provide a delightful Summer comfort to pregnant women and others who require scientific support.

In order to provide scientific uplift-support, a belt or corset must be made in two separate sections, so that the "lift" will come at the lower abdomen. Only SPENCER supports are made in two sections, to provide uplift instead of compression.

Not only is each Spencer garment cut and made individually for each patient—what is more important, a special design is created for that one patient alone, to meet the particular needs of her figure and her doctor's demands.

Spencer Summer Supports provide the same efficient support that Spencer garments of heavier material do, and like them they can be laundered as easily as lingerie.

A Spencer garment is the most economical garment a doctor can prescribe because it is *two garments in one*—an efficient surgical support and a style garment. Easily washable, long-wearing and comfortable.

Trained Spencer Corsetières are resident throughout the Kingdom. Name of nearest gladly supplied on request.

A scientifically trained Spencer Corsetière will call at your Surgery or at your patient's home to take measurements under your supervision. Spencer Supports and Corsets are never sold in shops.

Salt and Son Ltd.

Solve the Summer problem

Warm weather, though welcome, nevertheless has its inconveniences for many patients. The ordinary type of stocking has serious drawbacks during hot weather and, realising this, Salt's now make all grades in a special weave which, by its perforated finish, allows free passage of air to the limb thus avoiding excessive perspiration. All the essential supporting qualities are retained, however, so that the Open Weave Summer Hosiery is quite as efficient as the Winter type. The saving in weight and the delightful coolness is greatly appreciated by the patient. Owing to the increase in weaving the cost of this Summer Hose is fractionally more, but this slight extra is more than counterbalanced by the fact that the Winter Hose can be returned for necessary cleaning and repairing, so lengthening its life. A descriptive illustrated catalogue of all types of Elastic Hosiery will be sent on request.

SPHAGNOL PREPARATIONS

For insect bites and all forms of skin inflammation and irritation.

When anyone is bitten by insects or painfully sunburnt, the natural instinct is to scratch. Generally this makes the trouble worse, the sore place often turning septic. You must stop the itching with a cooling ointment before the patient will leave the tender spots alone, and give them a chance to heal. Smear on some Sphagnol Peat Ointment, which is both soothing and antiseptic. It cools and relieves at once and helps very much in dispersing the poisons which cause the irritation and swelling. In a short time the skin becomes normal again.

We should very much like to hear your opinion of our products. Please send for free samples to Peat Products (Sphagnol) Ltd., Dept. B105, 21, Bush Lane, London, E.C.4.

THE NATURAL MINERAL WATERS
OF
CARLSBAD
Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act:

(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.

(2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of
Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary organs.

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents:

INGRAM & ROYLE, Ltd.,
BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.
And at LIVERPOOL and BRISTOL.
Samples and Descriptive Pamphlet forwarded on application.

INTESTINAL DYSPEPSIA & FLATULENCE

An efficient intestinal germicide must be non-irritant, of low toxicity and maintain its power in the presence of faeces. In the treatment of Alimentary infections and toxaemias, particularly when of streptococcal origin,

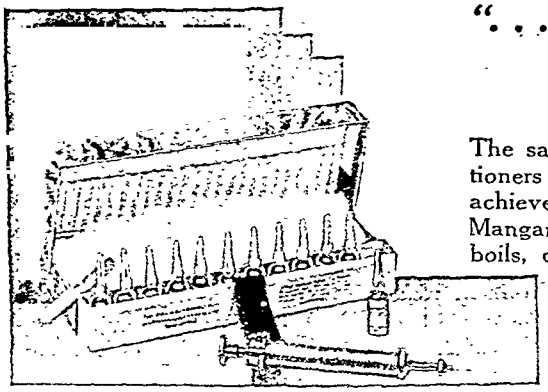
MONSOL INTESTINAL CAPSULES

are prescribed with success, because they possess these properties in high degree. They may be employed in large dosage over long periods without unpleasant sequelae.

Practitioners are invited to write for further particulars, samples and medical reports.

MONSOL LIMITED,
Vincent House, Vincent Square, S.W.1.

ACRIFLAVINE 'B.D.'



In the course of his practice the physician is in daily contact with cases for which antiseptic treatment is essential, as, for example, wounds of every description, burns, local septic conditions such as suppurating ear, eczema, pediculosis, and scabies as well as internal septic conditions; for use in all such conditions Acriflavine 'B.D.' is admirably suited as the following statement by a physician in general practice indicates:—

". . . I find Acriflavine 'B.D.' the finest antiseptic yet discovered. I use the emulsion, tablets, solution and suppositories and get excellent results with them all."

". . . I have never had a failure with it"

— — — M.B., Ch.B.

The satisfactory—sometimes described by practitioners as "dramatic"—results which have been achieved by the intramuscular injection of Manganese Butyrate B.D.H. in the treatment of boils, carbuncles, abscesses, chronic ulcers and similar conditions, have led to the extension of its sphere of usefulness, with the result that according to the statement of a well-known practitioner it is regarded as a sheet-anchor when treating acute staphylococcic and streptococcic conditions; indeed, as stated above, *he has never had a failure with it.*

DIMOL mouth wash

The best line of defence against all PATHOGENIC GERMS introduced by air or food.

As an oral wash and throat gargle ten drops in two ounces of water.

As a specific against thrush, mouth ulceration, and gingivitis ten drops in two drachms of water applied with cotton wool swab.

FRAGRANT ● POWERFULLY BACTERICIDAL ● NON TOXIC

It meets every requirement of dealing readily with infected ORAL and THROAT AREAS.

For particulars and prices write to:—

DIMOL LABORATORIES, LTD., 40, LUDGATE HILL, LONDON, E.C.4

HORLICK'S MALTED MILK IN DIGESTIVE DISORDERS

In diseases and disorders of the gastro-intestinal tract—gastric and duodenal ulceration, acute and chronic gastritis—it is essential that the diet should be bland and soothing. The food should be in a fine state of division, and care must be taken to avoid constituents which may irritate the mucous membrane. HORLICK'S MALTED MILK is constantly being recommended for use in these conditions. Composed of full-cream cows' milk combined with the soluble extracts of malted barley and wheat, it meets the requirements of both doctor and patient, since it contains nothing to cause mechanical irritation, or to excite a secretion of mucus. It is easily prepared and permits meals of small size at frequent intervals to be taken by the patient in an agreeable and palatable form. HORLICK'S is also an excellent vehicle for the addition of other items such as eggs to the dietary. HORLICK'S MALTED MILK has also been used with marked success in epidemic diarrhoea and dysentery.

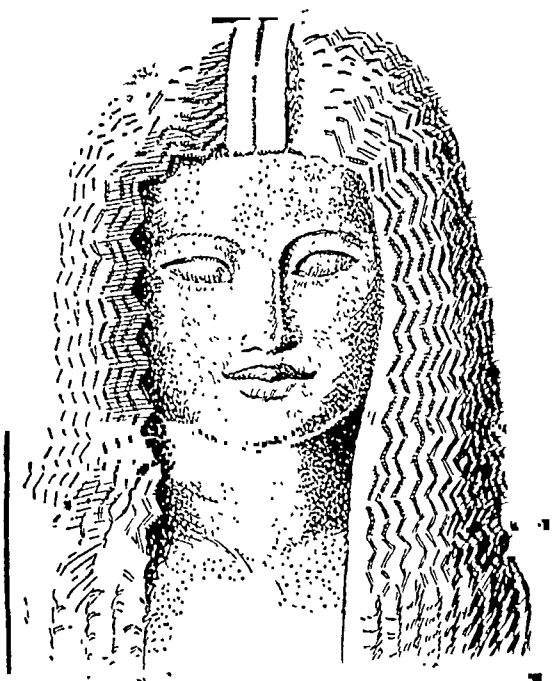
OVALTINE

FOR THE AGED

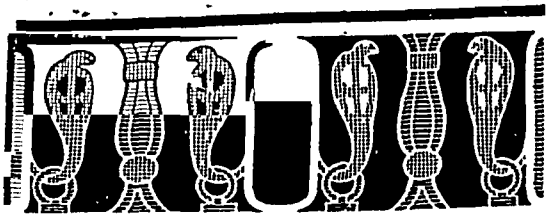
"Ovaltine" is delicious sustenance for old people. It sustains life ideally by giving tone to the tissues and promoting the healthy activity of the bodily functions.

"Ovaltine" provides complete nourishment in easily assimilable form. Its use greatly increases the nourishing value of other foods. The digestibility of milk, for instance, so largely used in old age, is increased two-fold by adding "Ovaltine" to it, while the starch in the cereals is converted into easily assimilated malt sugar by the enzyme diastase which "Ovaltine" contains in abundance.



"Ovaltine" is purin-free. Its use, therefore, neither aggravates nor favours the accumulation of uric acid in the system, nor leads to kidney disorder or gout. The tendency to constipation, so common in old age, is avoided by the use of "Ovaltine."

"Ovaltine" replaces to great advantage the usual meal-time beverages, tea and coffee, which are valueless as sources of nourishment and often contraindicated in senility.



A liberal supply for clinical trial sent free on request.

USE AND RECOMMEND IT FOR YOUR PATIENTS

The CONFIDENCE of the Medical Profession

Benger's Food has gained its great reputation by the constant recommendation of Medical Practitioners.

By its unique self-digestive action Benger's Food scientifically adjusts fresh cow's milk, diluted or undiluted, to suit the individual needs of a patient. In this respect it is different from any other Food obtainable.

Benger's is largely used as a routine treatment in all cases of impaired digestion. The following comments, recently made, indicate some of the specific conditions for which the Medical Profession prescribes Benger's Food.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."
"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."
"cancer of the stomach — doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."
"invariably used for invalids & aged persons."

A Physician's sample will be sent post free to any member of the Medical Profession.

'ZYMINE' Peptonising Tubes

(FAIRCHILD)

For the preparation of Peptonised Milk and other Predigested Food for the Sick.

'Zymine' Peptonising Tubes have been in use since 1882, making it possible for physicians to assure proper nutrition to their patients, even in cases where digestive power has been reduced to its lowest terms, and enabling chronic dyspeptics, invalids, convalescents, etc., who must live upon fluid foods for more or less prolonged periods, to take milk in quantities sufficient to maintain nutrition and promote restoration.

PEPTONISED MILK presents all the nourishment of plain milk freed from the objectionable qualities which constitute so serious a drawback to the utilisation of milk in the feeding of the sick. And of the many methods employed to make milk an available food for the sick, there is none that approaches the 'Fairchild' peptonising process in the certainty with which it accomplishes the desired purpose.

Supplied in boxes containing 6 and 12 Tubes.

The contents of one Tube will peptonise one pint of milk.

Originated and manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),
NEW YORK and 65, Holborn Viaduct, LONDON, E.C.1.

SAFETY or Baby!

Be warned by this bitter experience

Extract from "THE MANCHESTER GUARDIAN"
January 9th, 1933.

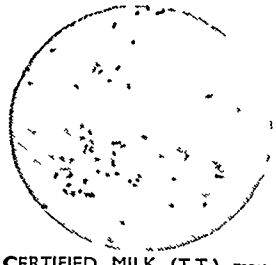
To the Editor:

Sir,

Most of your correspondents take it for granted that cow's milk is a natural food for infants in its raw state. Certainly we have found it the most useful and adaptable of foods, but with most infants care has to be exercised in its use and fruit juices are usually added to the infants' diet, whether the milk is raw or pasteurised

My own experience of the dangers of raw milk is, I think, a more telling one than Mr Barrow's is of pasteurised milk.

Some years ago I was in the habit of giving my child of two fresh milk in the evening. It was almost warm when we received it, but I had not then heard of any danger from bacilli. The child sickened and died of tubercular meningitis.

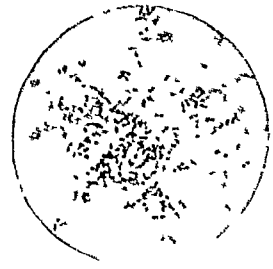


Only three weeks afterwards I received a circular issued by the Manchester Public Health Department recommending the boiling of all milk owing to the prevalence of tubercular infection, especially after measles and whooping cough.

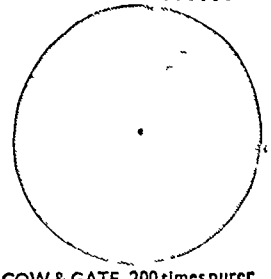
Had I known beforehand of this danger I have no doubt my child's life would have been saved. There must still be many mothers unaware, although nowadays the clinics have done much to instruct them, of this danger.

Yours etc.,
An Interested Mother.

The microscopic slides below prove that COW & GATE is the ONLY Safe Food for Baby when Natural Feeding fails. COW & GATE is the purest and freshest English Milk rich in vitamins and the essential minerals. All babies love it and it is SAFE. COW & GATE Chocolate Milk—equally safe—is an ideal daily diet for older and growing children.



GET COW & GATE TODAY!



CERTIFIED MILK (T.T.) may legally contain up to 30,000 germs per cubic centimetre.

PASTEURISED MILK may legally contain up to 100 000 germs per cubic centimetre

ORDINARY RAW MILK often contains more than 15,000 000 germs per cubic centimetre.

COW & GATE. 200 times purer than the finest Certified (T.T.) Milk, the highest grade of raw milk.

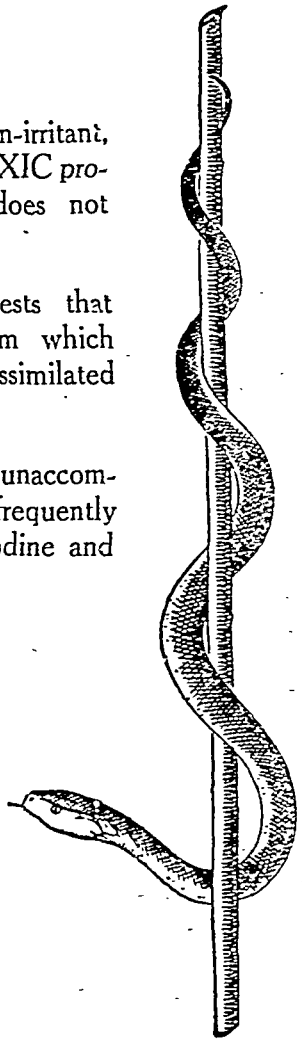
THERAPEUTIC NOTES

from

Oppenheimer Son & Co. Ltd.



Iodine Therapy

"ALPHIDINE"

ALPHIDINE is a non-irritant, *relatively* NON-TOXIC product of Iodine which does not cause Iodism.

Clinical experience suggests that the Iodine is in a form which is readily taken up and assimilated by the Thyroid Gland.

Its administration is unaccompanied by depression so frequently caused by the ordinary Iodine and the Iodides.

INDICATIONS:—All those conditions arising from a subnormal Thyroid.

HYPERTENSION, ARTHRITIS,

RHEUMATIC CONDITIONS generally.

Also valuable in fatty infiltration.

When nature defaults

a food with the attributes of human milk is needed.

(1) The proportion and state of sub-division of the fat,

(2) the nature and physical state of the proteins,

are of the first importance.

"Allenburys" No. 1 Modified Milk Food is specially adapted to the first weeks of infant life; the fat and protein are held in colloidal suspension with lactose and dextrin maltose.

■ ■ ■ ■

As development proceeds

the needs of the growing infant call for increased amounts of mineral elements; these with small variations in the proportions of fat, protein and soluble sugars form the *raison d'être* for the use of "Allenburys" No. 2 Modified Milk Food from the beginning of the fourth month.

■

This announcement regarding the "Allenburys" Foods is No. 11 of a series which will be continued.

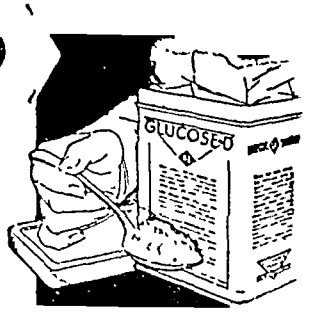
O O O O O

ISIS, ONE OF THE PRINCIPAL DIVINITIES TO WHOM THE ANCIENT EGYPTIANS APPEALED IN SUFFERING.—Isis was extraordinarily beloved and venerated throughout Egypt as a beneficent, healing goddess and as the ideal wife and mother. Healing was obtained of Isis in various ways; by prayer, such as, "O, Isis! Thou great enchantress, heal me, save me from the evil things of darkness, from the epidemic and deadly diseases and infections of all sorts that spring upon me"; through dreams, by incubation in her temples; by pronouncing her "words of power"; by wearing her amulets and possessing her talismans. The illustration shows Isis wearing a vulture head-dress with the uræus and a crown which consists of a seat or throne, the symbol of the sound of her name. She holds in her left hand the symbol of life while the right embraces her husband, Osiris.



Date: From c. 4000 B.C. The illustration c. 1500–c. 1350 B.C.

The debilitated patient and the athlete

Even these extremes meet in their need for:
(a) immediately accessible energy, i.e., glucose;
(b) elements to nourish and control their nerve cells and reflexes, i.e., calcium and phosphorus;
(c) vitamin D to ensure the assimilation of these elements.

Glucose-D is richly supplied with all these components. Whenever glucose is prescribed—whether as a therapeutic agent or as a product for everyday use, as a remedy for acidosis or a source of nourishment in fevers, as additional energy during periods of physical and mental strain or a "nutrient tonic" for debilitated adults and children—Glucose-D, the reinforced calcium vitamin glucose, is the preparation of choice. 1 lb. tins—1/9 7 lb. tins—10/6

GLUCOSE-D

An ante-natal routine

Could any ante-natal routine be more definite—or simpler?

The expectant mother—following a procedure in force in leading hospitals and ante-natal centres—takes one capsule of Adexolin a day during the last 100 days of her pregnancy. In this way she takes every day a precisely measured amount of vitamins A and D in natural proportions

The vitamin A of Adexolin serves to protect the mother against puerperal fever and to fortify the resistance of the foetus to neo-natal and infantile infections.

Adding the calcium-regulating vitamin D helps to preserve her teeth from decay and to promote normal skeletal development in the unborn infant.

Each 3 m. capsule of Adexolin contains 20,000 units of vitamin A and 1,000 International units of vitamin D. The protective and mineralizing effect of both vitamins can be secured with certainty by giving one Adexolin capsule a day during the last three months before confinement.

Boxes of 100, 8/6. Also in tins of 500 & 1,000.

An Address
ON
THE TREATMENT OF ALLERGIC DISEASES IN GENERAL PRACTICE*

BY
GEORGE W. BRAY, M.B., M.R.C.P.
ASTHMA RESEARCH SCHOLAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET
(Working with a grant from the Asthma Research Council)

An individual is said to be "allergic" when he manifests an exaggerated susceptibility to substances innocuous to normal persons in the amounts commonly encountered. This hypersensitiveness or "allergy" on the part of the sufferer to many usually harmless articles commonly contained in his diet or environment manifests itself in such numerous and apparently diverse conditions as asthma, hay fever, eczema, urticaria, and migraine, as well as in an ever-increasing host of minor affections.

At first it was thought that only protein substances could act as "allergens" or originators of these reactions, but recent observations have shown that many non-protein factors, such as carbohydrates, drugs, and even physical agents, can lead to identical reactions. When we analyse these allergic responses we find that they usually originate in one of two ways, either as a definite inheritance of the predisposition to manifest a specific hypersensitiveness of some type to some substance, or acquired as the result of tissue damage or excessive irritation. During childhood the chief aetiologic factor is the hereditary tendency, which can be demonstrated in from half to two-thirds of all cases; but in the majority of adults post-natal factors have been particularly severe and constant—for example, the continual association with a particular allergen either by occupation or by environment, combined possibly with extensive tissue trauma. Such a mode is exemplified in cases in which asthma has followed such lung damage as pneumonic processes complicating infections, in which a succeeding sensitization occurs to feather pillows or horsehair bedding on which the patient has lain during the illness, or in cases in which paroxysmal rhinorrhoea follows some nasal infection upon which a sensitization to dust, animal emanation, or face powder later develops. Such a division of cases, if possible, into primary (or hereditary) and secondary (acquired, or post-traumatic) is of great importance in determining the causative allergen, as the latter group is practically always inhalant or occupational in nature. For this reason a thorough history of the time and mode of onset is essential.

Allergic diseases have several characteristics in common. They are essentially periodic in nature, with apparent intervals of complete freedom. Symptoms generally have their onset during the night, or are most distressing during those hours. They have their maximum age at onset during childhood or adolescence—with the exception of hay fever—and each manifestation appears to have definite sex and seasonal variations. Besides the common history of allergic complaints obtainable in relatives or offspring, the patients usually give an account of some other allergic manifestation in their present or previous history. Finally, allergic diseases are greatly affected by varied states of health of the sufferer, and especially by indigestion, menstruation, and pregnancy; by intercurrent disease such as fevers, exanthemata, or following operations; by emotion, excitement, or exhaustion; or by a change of climate, locality, altitude, or environment.

Their treatment involves a very definite routine, so that reliance on one therapeutic agent for all cases, irrespective of their aetiology, or the "shot-gun principle" of an assemblage of many in the hope that one will hit the mark, is to be deprecated. Again, the treatment sought from the specialist differs from that sought from the general practitioner, for whereas the latter is commonly called from his slumbers to relieve each acute exacerbation, the former is generally consulted during periods of relative freedom as to the means of preventing further relapses. I hope to show how the general practitioner can combine both functions.

* Read before the Leicester Medical Society.

ASTHMA

In the treatment of asthma, as in all allergic diseases, the first essential is to determine the cause. Often this will be indicated if a careful history is taken, but in other cases no clue is afforded, and skin tests, or the use of elimination diets, are advisable. But for the general practitioner skin tests are not practicable owing to their cost, the question of which to use, the number necessary, the technique required, and, in general, the impotency and worthlessness of proprietary preparations.

It is easier for the practitioner to make sure that the sufferer avoids the common agents that lead to attacks, which are either of an inhaled or ingested nature. The inhalants are the more common cause of allergic reactions at all ages except infancy, when foods predominate, and include feather, down, and horsehair pillows and bedding, animal pets, house dust, and orris root, the basis of all common cosmetics and toilet preparations. To remove these irritants the patient's pillow, mattress, bolster, and eiderdown should be filled with the best Java kapok, which can be obtained from the Witney Blanket Co. of Witney, Oxon. Animal pets should be kept out of the house, and always away from the sufferer, and children should not have toys stuffed with animal hair. House dust is difficult to eradicate; the bedroom should be well ventilated, with a minimum of ledges, carpets, curtains, and other dust-holding surfaces; the furniture should be scanty, and of the plain wooden type rather than upholstered; cleaning should be done with some electrical suction apparatus in preference to the common methods of dusting, which disperse the dust through the atmosphere; and, if cloths must be used, they should be damp, so that the dust can adhere, and the process should be carried out at times when the asthmatic is away from the house. Orris-root-free cosmetics may be obtained from Messrs. Boutalls, Ltd., chemists, 150, Southampton Row, London, W.C.1.

Dietetic Principles

If skin tests are not available to determine causative foods the simplest procedure for the practitioner to adopt is the prescription of a diet which is free from the common causes of asthma. In such a diet wheat, barley, and oats should be avoided as much as possible, and the remaining cereals should be employed after heating, puffing, or toasting. It should exclude egg and foods containing egg—especially egg-white. In many cases egg-yolk, if freed from white, can be used. It should avoid cow's milk in its natural state. The lactalbumin is commonly the part that leads to the reactions, and, as it is heat-coagulable, if the milk is well boiled, cooled, and the coagulated scum which forms removed, it can frequently be tolerated. Allergilac (Cow and Gate, Ltd.) is a lact-albumin-freed, half-cream, acidified dried milk that is applicable in cases of *milk sensitivity*. Condensed and evaporated milks can be used at times, as they have been modified to some extent by prolonged exposure to heat. Vegetable "milks," as can be made from soya bean flour, are useful at times. The diet should avoid beef, and especially pork, ham, bacon, and lard. It should also avoid many other less common foods that do not agree

with asthmatics, such as shellfish, nuts, cocoa and chocolate, fruits, such as fresh strawberries, apple, and banana, and vegetables, such as beans and peas, potatoes, and tomatoes, cabbage, and celery. Such a basic diet for an asthmatic child is set out below, and it is easy to modify it for an asthmatic adult. The patient is placed on the diet until free from symptoms, then one of the excluded foods is added each few days until symptoms recur, when generally the latest addition is the causative food. But this does not mean that it is the sole food, for patients are generally multi-sensitive, so that the process must be continued until all the excluded foods are reintroduced except those that lead to reactions.

BASIC DIET FOR AN ASTHMATIC CHILD

Breakfast

Vitamins.—Some concentrated preparation as adexolin, ostelin, or radiostoleum. Orange juice, grape fruit.

Cereal.—This should be made with water, covered with prunes or other cooked fruits and their juice, and sweetened. The following are advised in this order of preference: tapioca, sago, arrowroot, rice (boiled, puffed, toasted flakes, or "crispies"), rye (crisps or toasted flakes), corn (flakes or "post-toasties").

In place of wheaten bread—ryvita crispbread, oatmeal biscuits, or very thin crisp toast. Buttered when cold, and covered with honey, treacle, or syrup.

Beverage.—Allergilac (Cow and Gate, Ltd.), or a small cup of warm, weak tea, with a small teaspoonful of condensed or evaporated milk.

Dinner

Soup.—A small quantity of clear, sieved bone and vegetable soup.

Meat.—Lamb chop, grilled or stewed, or roast lamb. Brains. Chicken or other poultry. Occasionally steamed or boiled fish.

Vegetables.—Sweet potato, turnip, carrot, sprouts, soya beans, squash, artichoke.

Salad.—Beetroot, lettuce, watercress, or asparagus tips covered with olive oil or lemon juice.

Sweets.—Baked or stewed pears, peaches, or apricots. Custard made from powder, not egg. Fruit jellies. Tapioca or other pudding, cooked with water, not milk. Dates or dried figs, soaked in water for forty-eight hours.

Tea

Soup.—Bone and vegetable or other clear soup.

Cereal.—Ryvita, oatmeal biscuits, or crisp toast, with butter or margarine and honey or seedless jam.

Sweet.—Stewed fruit or fruit jelly, or other simple dish prepared with gelatin.

Beverage.—Allergilac. Tea with condensed or evaporated milk.

Other Measures

Besides the avoidance or removal of common specific causes there are several contributory factors that need our attention. The sufferer should not be confined to bed except in the presence of fever, or progressive loss of weight), for confinement to house or bedrooms tends to prolong attacks. Asthmatics should always be allowed up and about when the weather is fine. A warm or tepid morning bath should be followed by a cold sponge and a brisk rubbing with a rough towel; hot evening baths commonly provoke attacks. In avoiding constipation drastic purgatives are not advisable, especially the common "once or twice a week" kind, which are usually taken overnight; an early morning saline, or glass of fruit juice, is preferable. Among poorer children the hot bath and dose of syrup of figs on a Friday night are the commonest causes of week-end asthma.

In addition to the avoidance of specific foods to which the patient is hypersensitive, the diet of the asthmatic patient should be regulated according to such complicating conditions as gastric anacidity, flatulence, and over- or under-feeding. Gastric or rectal distension commonly precipitates an attack, so should be avoided. Flatulent dyspepsia and chronic gastritis are common, and may be alleviated by ensuring thorough mastication, by gastric lavage each morning with a dilute solution of hydrogen peroxide, or by administering dilute hydrochloric acid by the mouth—one or two aklorep tablets, placed on the tongue and swallowed with a little water, immediately before meals (made by Roberts and Co., 76, New Bond Street, W.1). Three small, easily digested, simply compounded meals a day are best—a good early breakfast, a substantial hot midday meal, and a light early supper several hours before retiring should be the rule. Late meals, heavy meals, bulky diets, or mixed cooking should be avoided. No food or drink should be taken after supper, and especially not just before or after getting into bed.

Reflex irritation may precipitate asthmatic attacks, so that foci of infection should be removed. With regard to nasal abnormalities, it is essential to realize that they are commonly the result of allergic reactions, and rarely a primary cause. It is pitiful to hear of the number of useless operations that many asthmatics have had on their noses. Whilst infected tissues should be removed or drained, boggy tissues will usually subside following therapy based on allergic principles. It should be remembered that a function of the turbinals is to warm and moisten the inspired air, so that after their removal asthmatics are particularly prone to attacks from breathing cold air, and we are at a loss to help them further. Though occasionally asthmatics show evidence of endocrine dysfunction statistics bear out the fact that such dysfunction is rarely the primary cause of the asthma. In asthma commencing at the menopause thyroid and ovarian substance are frequently beneficial adjuvants. The common mental states that precipitate attacks of asthma are emotion, exertion, and excitement, so that these should be guarded against. Fussing and over-anxiety should be avoided, and attempts made to divert the sufferer's attention into other channels. Other less common psychic factors include grief, fear, mental depression, sex conflict, or worry.

The majority of asthmatics look forward with some apprehension to the night, and often when changing from a warm sitting-room to a cold bedroom an irritating cough is initiated. It is therefore advisable to give a sedative in the form of a strong linctus at bedtime each night. For children I order:

Compound tincture of camphor ...	20 minims
Tincture of stramonium	5 minims
Pure dextrose	30 grains
Oxymel of squill	15 minims
Chloroform water	to 2 drachms

At bedtime.

To adults I give:

Tincture of stramonium	15 minims
Syrup of Virginian prune... ...	to 2 drachms
Syrup of codeine phosphate ...	

Early morning breathing exercises, especially of a counting, humming, or hissing type, are very beneficial if not continued up to the point of fatigue. They teach the sufferer to concentrate on breathing out rather than breathing in; they train the diaphragm and abdominal muscles to contract properly and harmoniously; and they counteract the tendency to chest deformity. Slow walking in the open air, at first on the flat and later on mild hills also assists. As regards climate, the sufferer should be shielded from extremes of temperature, draughts, cold winds, and fog. From experience it has been found that the east and south-eastern coasts are generally bad for sufferers as places of dwelling, or for convalescence or holidaying. The south and south-western coasts are preferable.

Desensitization and Drugs

If after this detailed routine has been carried out for a few months the patient has failed to improve appreciably then desensitization should be attempted. When employed it should be specific—that is, against the causative allergens—if possible. As these are most commonly inhalant, a mixture of the common feathers, hairs, dusts, and orris root is more likely to meet with success than is a shot in the dark, such as the use of a non-specific agent entails. In practice, both in adults and in children, I use this inhalant mixture solely and in very concentrated dosage. Among the non-specific agents Witte's No. 30 peptone is probably the best. Autohaemotherapy is successful occasionally. Tuberculin, milk, and vaccines are in general a waste of time and money. Physico-therapeutic methods, such as electrotherapy (diathermy), actinotherapy (ultra-violet and infra-red rays), and *x*-ray therapy should only be employed in rare cases where clinical and radiographic signs justify their use. Among the drugs ephedrine is widely used, and frequently lessens the severity of attacks, but never cures or entirely prevents them. Aspirin wards off attacks in some cases, but in others precipitates them. Glucose helps some cases. Calcium is of no value; many patients have idiosyncrasies to iodides.

SEASONAL HAY FEVER

In England the pollen cloud abounds from the end of May until the end of July, and corresponds principally with the period of pollination of the grasses. In contrast with other parts of the world trees and weeds are relatively unimportant factors. Flowers and cereals are often incriminated as causing symptoms, but the former are insect- not wind-pollinated, and the latter produce such large, heavy, sticky granules that they cannot be carried far by the wind. Hence, flowers and cereals can only be a cause of symptoms when the susceptible person is brought into contact with them either by occupation, in the adornment of the home, or by direct inhalation, as in actually smelling the flowers. The successful treatment of seasonal hay fever depends rather upon the recognition of all possible allergic causes than upon the detection of infections or structural alterations in the nose. No doubt the existence of the latter tends to accentuate hay fever symptoms when present, but if all the specific causes are recognized, and measures taken to render them void, the patient should be just as immune to symptoms in the summer as he is in the winter. In the absence of surgical intervention it is remarkable that patients can suffer from hay fever symptoms for many years without infection developing. The specific causes of hay fever include not only the pollens of the locality but also feather pillows, house dust, animal hairs, and orris root cosmetics. If the patient is sensitive to these latter inhalants their removal or substitution is essential, or desensitization necessary; and it is the recognition and removal of these other inhalant sensitizations that frequently makes the difference between a failure and a successful treatment.

The solutions of the common British pollens for testing and treatment may be obtained from Messrs. Duncan, Flockhart and Co. of 155, Farringdon Road, London, E.C.1. Skin tests are carried out with the common pollens of the district, and the solution for treatment should contain all the pollens to which the patient reacts. In the British Isles they are practically only grasses, though in special cases isolated reactions occur to trees and weeds. The most frequent reactions amongst the grasses occur to Yorkshire fog (*Holcus lanatus*), the meadow grasses (*Poa annua, pratensis,* and *trivialis*), the fescues (*Festuca ovina* and *elatior*), and to Timothy grass (*Phleum pratense*). For those that cannot afford the time and expense of a prolonged change of environment in order to avoid the pollens to which they are sensitive, desensitization is a necessary therapeutic measure. Once symptoms have commenced one is forced to undertake co-seasonal treatment, and a satisfactory course can be put through by giving injections of increasing doses of pollen solution each two hours from 8 a.m. to 8 p.m. In known cases the pre-seasonal method is that usually adopted, the course of injections commencing about the beginning of March and continuing weekly until the beginning of June. Once the maximum dosage has been reached it is often advantageous to continue the treatment perennially. In such a case one injection of the maximum dose reached at the end of the season is continued each month, and the patient is kept permanently immune for about three years, by which time all sensitivity is frequently lost. The injections may be continued over a period of years without leading to any functional or organic disturbances. Two-thirds of the cases derive great benefit immediately from the treatment, provided that it is carried out with thoroughness. The common causes of failure include: incorrect diagnosis; improper treatment, due to impotent extracts, insufficient injections, or inadequate dosage; failure to recognize multiple sensitizations to factors other than pollens; and seasonal variations in the pollen crop, leading to an extreme abundance of pollen at a given time.

Besides the preventive measures outlined there are many palliative measures that bring great relief to sufferers during the season. The eyes can be relieved by the wearing of dark glasses, which cut out the glare and diminish the amount of pollen coming into contact with the conjunctival mucous membrane. The itching and burning of the conjunctival and nasal mucous membranes can be relieved by the following ointment:

Benzocaine	1 drachm
Ephedrine hydrochloride	10 grains
Sol. adrenaline hydrochloride *B.P.*	1 drachm
Soft white paraffin	to 2 ounces

or by the use of anesthone cream (Parke, Davis and Co.).

Internally, ephedrine hydrochloride in doses of half to three-quarters of a grain orally, night and morning, is often sufficient to control the spasms, but in acute exacerbations the hypodermic injection of adrenaline solution is often necessary. Hydrochloric acid has a beneficial effect if given internally; this is best given in tablet form, one aklorep tablet three times a day immediately before meals. Inhalations of carbonic acid gas through a sparklet apparatus, as suggested by Hurst, frequently lead to an immediate cessation of nasal symptoms. Cauterization and ionization of the nose do not generally lead to any permanent benefit, though at times they are useful as palliative measures. Vaccines and non-specific therapy are again generally a waste of time and money.

PERENNIAL HAY FEVER

In many cases hay fever symptoms are present more or less all the year round, and are not restricted to the months of May, June, and July. In these cases symptoms are due to causes other than pollens. These include the common inhalants already described; such foods as wheat, egg, milk, chocolate, potato, and beans; drugs, of which aspirin is the commonest; and bacteria, though infection is the exception rather than the rule. Two additional factors, occupation and climate, play an extremely important part. Bakers develop symptoms from contact with cereal flours, though they are innocuous when taken in food form by mouth. Housewives are affected by house dust and moulds, feather and horsehair bedding, animal

emanations, and orris root toilet preparations. Chemists and doctors are affected by the powder of ipecacuanha and sodium salicylate. Rubber, shoe, and chemical workers are also frequent sufferers. A cold, changeable climate more often causes symptoms than a warm, equable one, and discomfort is more often experienced in the winter than in the summer, and especially on going from a warm room into a cold one. The treatment of perennial hay fever may be palliative or curative. The palliative treatment includes such intranasal applications as the inhalation of carbonic acid gas, the use of adrenaline, ephedrine, and cocaine nasal sprays and ointments, or the application of silver nitrate. Nasal cauterization and zinc ionization meet with occasional success, usually only temporary. Intranasal operations generally afford very little relief in the absence of sepsis. The curative treatment demands the active removal of sensitization factors, as determined by skin tests, or their passive avoidance by a change of climate or occupation. Desensitization is frequently necessary, and in inhalant sensitizations a mixture of feathers, hairs, dusts, and orris root offers the best chance of cure. If specific therapy cannot be applied one may employ the less beneficial injections of peptone or auto-serotherapy. Vaccines, either autogenous or stock, very rarely lead to any improvement.

INFANTILE ECZEMA

The treatment of infantile eczema may be discussed under two headings: the treatment of the local reaction, and the treatment of the cause.

The treatment of the local reaction depends upon the site of the lesion and upon the presence or absence of infection. The lesions are generally at different stages on the face, scalp, and body; some parts are infected, and others not. The first duty is to cleanse the surfaces, and for this purpose soap-and-water should never be used. For mild cases olive oil will suffice, but in the more severe ones a starch poultice will achieve the optimum effect. If, when the crusts have been removed, sepsis is still present, a yellow oxide of mercury paste such as the following is advisable:

Yellow mercuric oxide	15 grains
Starch, in powder	2 drachms
Zinc oxide	2 drachms
Soft paraffin	to 1 ounce

When the surface is aseptic the most useful preparations to apply are crude coal tar (1/2 drachm to the ounce) in the chronic lichenified type, and zinc paste if the surfaces are acutely inflamed and angry. If there is excessive lichenification of the skin the addition of salicylic acid (as in Lassar's paste) is advisable. Old dressings and crusts should always be removed with warm olive oil before applying new. Of equal importance with the cleansing of the surfaces and the application of medicaments is the placing of the child, as well as the part, at rest, and the prevention of scratching. A dose of nepenthe or chloral should be given at night, the face kept covered with a mask, and the elbows splinted.

The treatment of the cause involves in the first place its determination. In infantile eczema two factors are involved: the primary sensitization, and the secondary predisposing factors. As regards sensitization, most eczematous infants are sensitive to egg, whether they have ever partaken of it or not, probably due to a sensitization in utero. Other food sensitizations depend to a large extent upon the feeding of the child at the time. During the breast-feeding period, egg, milk, cocoa, wheat, or cottonseed may be factors, owing to the habit of pregnant and nursing mothers supplementing their diet with milk foods, ovaltine, cocoa, porridge, or lactagol. In such cases a careful history will frequently indicate the causative food. In the weaning stages milk protein becomes the chief offender, and in the majority of instances it is the lactalbumin fraction that is at fault. Fortunately, as already pointed out, this is a heat-coagulable protein, so that often a modified milk, such as condensed, evaporated, or acidified milk, can be used. As in cases of asthma, allergilac is very beneficial in milk-sensitive children. A similar milk can be prepared at home by boiling the milk for fifteen minutes, allowing it to cool, removing the scum, and acidifying by adding to each pint 40 minims of dilute hydrochloric acid (*B.P.*), drop by drop, whilst stirring. The requisite amount is just brought to blood heat for each feed. Children appear just as sensitive to goat's milk as to cow's. Vegetable "milk," such as may be made with soya bean flour, does not lead to such good results as the modified acidified milk. When the child commences on his baby diet such additional factors as wheat, oats, barley, bacon fat, orange, beef, potato, spinach, and corn arise. Finally, a large percentage do become, or are, sensitive to feather or horsehair bedding, so it is as well to see that the best Java kapok is installed in the cot, and animal pets and toys stuffed with hair are excluded.

Apart from these primary factors, and especially when the condition has lasted for any length of time, the skin gets into such a state that it appears to be irritated by numerous secondary non-specific, non-allergenic causes, which include (*a*) such external irritants as woollen garments, trauma, infection, mechanical irritation, chemicals (such as strong soap and various therapeutic applications), changes in temperature, and exposure to winds; and (*b*) such internal derangements as accompany teething and overfeeding. Each of these factors must therefore be considered and nullified as far as possible.

PAPULAR URTICARIA

Probably the commonest type of urticaria met with in general practice is the papular urticaria of childhood. It is extremely prevalent in England, forming at least 10 to 20 per cent. of all out-patient skin cases at children's hospitals. Very few children escape without having it in some degree. Everyone is familiar with the pea-sized red blotch that appears on the covered parts of the body, in the centre of which a minute papule or vesico-papule later develops. The wheal soon disappears, but the papule lasts several days or weeks, especially if excoriated as the result of the intense nocturnal itching. Practically all children develop lesions before the age of 5 years, and ordinarily the condition disappears before puberty, periods of quiescence being followed by relapses which are more or less confined to the warmer months of the year. Many theories have been expressed as to the aetiology. It has been thought to be a disorder associated with dentition ("gum rash"); an ill effect of vaccination; a disorder of digestion, associated with constipation, improper feeding, rickets, or the ingestion of certain acid fruits and sweets; a result of improper clothing, uncleanliness, or decomposition of sweat; a result of the bites of the flea, louse, or bed-bug; an association of worm infestations; and, finally, an allergic reaction to environment.

It is with trepidation that I suggest, as the result of studies in several hundred cases, a new aspect. In the majority of instances two factors are involved—one dietary, the other thermal. The dietary factor may be divided into two groups: (*a*) fats, especially bacon fat, which is a pronounced ingredient of a child's diet in this country; vegetable oils and fats, in Jewish children;

and cod-liver oil in a certain percentage of any nationality; and (*b*) common foods such as fish, egg, potato, oats, and chocolate in a small number of cases, as additional agents. Acid fruits and vegetables, though commonly incriminated, seem merely to aid the absorption of the nocuous fat. The thermal factor is also an important one, for the lesions generally appear only in the warmer months of the year, when the child is warm in bed at night, or following a hot bath, after exercise, or following any of the feverish ailments that are common in early childhood. The lesions cease to appear in the majority of cases when the fats outlined are removed from the diet, and when care is taken not to let the child get overheated. Though a rhubarb and soda mixture is commonly given I find a pepsin and hydrochloric acid mixture more beneficial. The lesions may be treated with naphthol ointment (1 per cent.) or 2 drachms of solution of coal tar to 8 ounces of calamine lotion. If the lesions are infected probably the yellow oxide of mercury ointment, outlined in the treatment of infantile eczema, is the best.

ENURESIS

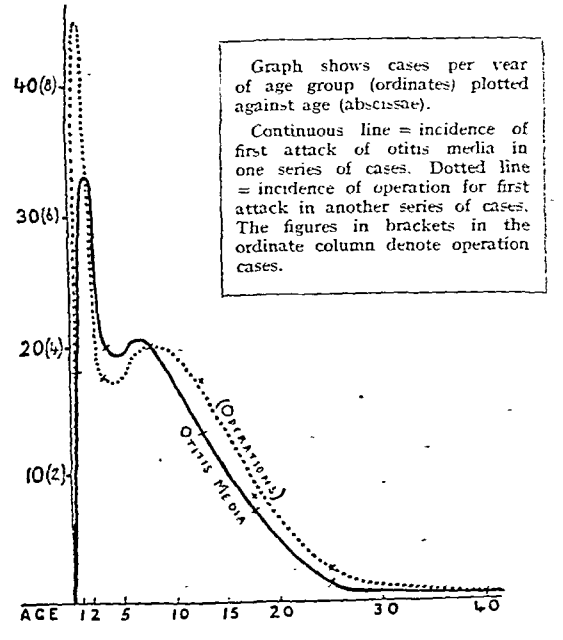
As enuresis is a common accompaniment of papular urticaria and many allergic conditions, and has ceased when treatment has influenced these other conditions, I was led to investigate many cases of enuresis that had persisted in spite of dietary and fluid restrictions, lifting at definite hours, and large doses of belladonna, and in which no urinary abnormalities could be detected. Many of these cases have been found sensitive to common foods, especially pig products, as well as to feather and horsehair bedding. The removal of these irritants, together with the administration of large doses of ephedrine by mouth, such as 1/2 grain at the child's bedtime (repeated when the mother goes to bed) nightly for some months, rapidly cures the complaint. The sphincter-tightening effect of ephedrine on the bladder is well recognized among asthmatics. As soon as any toxic effects of the drug such as vomiting, tachycardia, insomnia, or stupor are experienced, the dose is halved.

MIGRAINE

Migraine, or sick headache, is extremely common in members of allergic families, and especially in the mothers of asthmatic children. Besides these hereditary associations there is abundant evidence in favour of many cases of migraine having an allergic basis. That allergic reactions can occur in the central nervous system is shown by the cerebral symptoms that frequently follow injections of therapeutic serums. In addition, many cases give positive skin reactions, and the headaches cease when the causative allergens are removed. In the attack the patient is forced to lie down, and the room should be darkened, and an ice cap applied to the head. The bowels should be well opened with magnesium or sodium sulphate. Probably one of the best drugs to relieve the headache is compral (Bayer and Co.), three tablets being given each six hours. Others favour bromide and chloral, sodium luminal, caffeine, and veramon. In the preventive treatment the first duty is to remove specific allergens. The commonest are foods, and include milk, wheat, eggs, pork, chocolate, nuts, peas, and beans. A few sufferers are sensitive to inhalants, such as feathers and animal hairs. Biochemical investigations have indicated that migrainous attacks are associated with a change in the blood toward the alkaline side, so that this should be combated with a ketogenic diet, with marked restriction of carbohydrates, and hydrochloric acid by mouth. In cases markedly affected by menstruation, organotherapy is indicated in addition, such as pituitary, ovarian, and thyroid preparations.

OTORRHOEA *

BY



E. WATSON-WILLIAMS, M.C., CH.M., F.R.C.S.ED.

SURGEON IN CHARGE, EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY

Suppurative otitis media† begins in early life. Except as a complication of severe influenza, a first attack in adult life is uncommon. The importance of the very early years is brought out in the following table of ages of first attack in a consecutive series of cases. As a check on the "sample," it is only necessary to compare the corresponding figures for a quite distinct series of patients

Age Incidence of Otitis Media

Age	First Attack of Otitis Media		Operation for First Attack	
	Cases	Cases per Year of Age Group	Cases	Cases per Year of Age Group
0-1	18	18.0	9	9.0
1-2	33	33.0	14	3.5
2-5	60	20.0		
5-10	101	20.0	20	4.0
10-15	65	13.0	17	3.4
15-20	35	7.0	8	1.6
20-30	14	1.4	5	0.5
Over 30	13	0.4	3	0.1

Graph shows cases per year of age group (ordinates) plotted against age (abscissae).

Continuous line = incidence of first attack of otitis media in one series of cases. Dotted line = incidence of operation for first attack in another series of cases. The figures in brackets in the ordinate column denote operation cases.

for whom a mastoid operation was performed during a first attack of otitis[1]: the incidence was much greater during the *first* year than at any subsequent period, and in my experience this is constant. In neither series was there an abnormal proportion of influenzal otitis.

Two-thirds of first attacks of otitis occur between the ages of 3 and 14. Scarlet fever and measles, in conjunction with "adenoids," furnish the obvious explanation. But the incidence is as high during the first year of life.

* Delivered at a meeting of the Bath, Bristol, and Somerset Branch of the British Medical Association, January 25th, 1933.

† Throughout this paper *suppurative* otitis media is implied.

and much higher during the second ; and here such an explanation fails. A very common history is: "There was never any ear trouble before, except that his ears ran with every tooth he cut as a baby." And it must be conceded that the catarrhal reactions to teething, such as coryza, bronchitis, and diarrhoea, are the starting-point of a very considerable bulk of otitis media.

Why do children exhibit this catarrhal tendency and why do they develop adenoid hypertrophy? Repeated exogenous bacterial infection is cited in explanation, but it cannot be contended that this is convincing. Rather

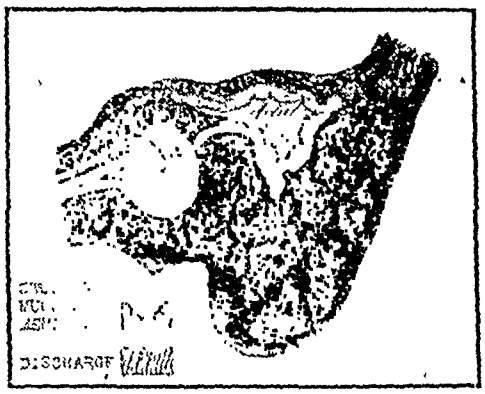


FIG. 1.—Vertical section of ear in plane of tympanum; position of membrane indicated. Cancellous acellular ("infantile") type of mastoid. At birth there is no real "process," but bone arrangement is that here shown, the antrum is higher, but as large as in adult life. Cell formation begins in second year, and is nearly complete by tenth. Occasionally this type of mastoid persists into adult life. Process smooth, cortex rather thin, interior cancellous, practically no cells.

are we disposed to inculpate a "constitutional" factor, and recent work strongly suggests that a relative hypovitaminosis is the real starting-point of these troubles. If this is so the prophylaxis of otitis—and therefore of the bulk of adult human deafness—lies in the hands of the physician during the earliest years of life. Admittedly, where chronic rhinitis or adenoid hypertrophy exists surgical treatment is generally necessary in addition to

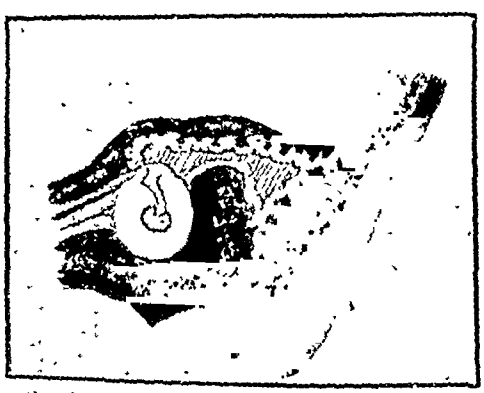

FIG. 2.—Similar section, incus and head of malleus removed. Sclerotic acellular type of mastoid (about 20 per cent. of adults). Process narrow, deeply grooved, concave above, cortex thick and dense, little cancellous bone, cell development poor.

medical, and the results as regard otitis media are as a rule strikingly satisfactory. Here I should like to digress to say that in my experience the removal of tonsils seldom benefits otitis media.

TREATMENT OF THE DISCHARGING EAR

The purpose of the present communication is, however, to discuss, not the prophylaxis of otitis media or the treatment of the acute phase before rupture or paracentesis of the membrane—a measure the value of which is well recognized—but the treatment of the patient whose ear is actually discharging. It is assumed that adenoids, nasal infection, and constitutional conditions are receiving treatment. Two points require consideration. First, in most cases the whole, or nearly the whole, of the middle-ear cleft is infected from the outset: some parts may recover more rapidly than others. Secondly, of those patients who receive no treatment at all the great majority recover completely. No doubt these cases include few of the more severe infections, but the point must be kept in mind when discussing the merits of any method of treatment.

The perforation in the membrane in a chronic case may be as large as in Figs. 2 and 3, but in an acute case it

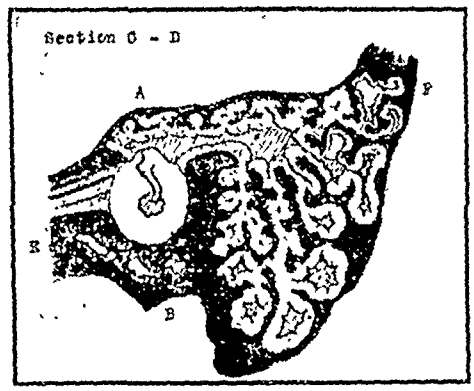

FIG. 3.—Section as Fig. 2. Common cellular type of mastoid. Process large and convex, cortex very thin, cancellous bone almost absent, cells numerous and complex (often less so than here shown). Note that the attic conforms to type of mastoid.

is more often minute, as in Fig. 1. The normally narrow slit of the tympanum is almost obliterated by swollen mucous membrane (Fig. 4), folds of which shut it off from the attic. This in turn is subdivided and nearly filled by the ossicles, their ligaments, and the reflections of mucous membrane which invest them (Figs. 4 and 5). The aditus is probably merely a potential channel during an acute infection, and beyond it lies the antrum with

FIG. 4.—Transverse section of same mastoid as Fig. 3, in nearly horizontal plane E-F. (F.R., foramen rotundum.)

its cells, generally numerous and complex, also lined with engorged mucous membrane, so that many are almost completely shut off even from the antrum (Figs. 3 and 4). The spaces that are left are filled with exudate, purulent for a day or two, but rapidly becoming glairy and mucinous. It is obvious that the scope of treatment via the meatus is strictly limited. The most we can hope to do is to promote natural drainage. We must carefully avoid anything which may increase congestion or the risk of additional infection, or which may damage the inflamed tissues, so that repair may be as rapid and complete as possible, with a minimum of scarring and damage to hearing—that is, essentially, damage about the oval and round windows (Fig. 4).

THE "WET" AND "DRY" METHODS

The closing years of last century saw a considerable controversy between two schools of teaching—the "wets" and the "drys." (Cf. *Lancet*, and *Laryngoscope*, 1899.) The "wets" had the advantages of tradition and of the more active treatment; they apparently retain a large body of adherents to this day. Syringing the ear with warm sterile saline is a tedious method of removing a viscid discharge, but unobjectionable: water, even when sterile, makes the skin sodden, and causes mucous congestion. Hydrogen peroxide alone or as an adjuvant to syringing acts mainly mechanically, its disinfectant effect being negligible. The bubbling exercises a mesmeric fascination over the lay mind. It is definitely irritant to mucous membrane, and causes many attacks of otitis externa. But the real disadvantage of these methods lies in the tendency to increase congestion, probably a more important matter than any risk of carrying infection into hitherto healthy areas. I have so often seen the need for immediate operation arise in cases, acute or chronic, directly following treatment on these lines, that I have long refused to countenance such for any patient with a perforated membrane.

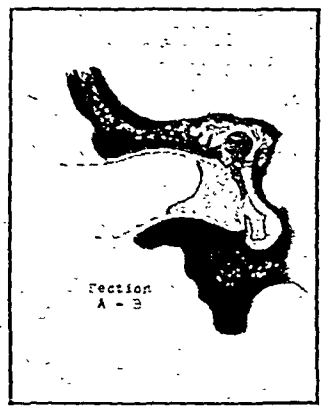

FIG. 5.—Vertical section across plane of tympanum, to show attic, Prussac's space, malleus, ligaments, etc.

Aqueous medicated "drops" are sometimes used, such as mercurochrome in 1 per cent. solution. This stains the membrane scarlet, and during the acute stage impedes observations on the progress of the disease. It is a powerful disinfectant, but the importance of disinfecting the meatus is possibly exaggerated, as the fundus is normally sterile. In the subacute stage mercurochrome often acts like a charm, though the chance of staining clothes and bedding is a nuisance. It should not be used for more than a fortnight since it is a definite tissue poison, and seems frequently to delay healing, which occurs when it is stopped. Another modern "wet" method is zinc "ionization." The ear is carefully cleansed and filled with 2 per cent. zinc sulphate solution. An anode of zinc wire is placed in the fluid and a current of 3 milliamperes applied for ten minutes: this may be omitted without influencing the result. The treatment depends really on cleansing and subsequent (chemical) surface coagulation. It is not recommended for acute cases; if applied to all "suitable" cases the results are as good as most, but very few which resist simpler treatment are cured by "ionization." The aura of mystery that surrounds all electrical treatment probably accounts for its vogue.

The "drys" treat the ear simply by inserting a loose pencil (not a plug) of sterile gauze or wool in the meatus, and changing it as often as it becomes soiled. The discharge is regarded as the best "dressing" for the inflamed mucosa. In the London County Council fever hospitals, where many hundreds of acute otitis cases are treated every year, the *only* local treatment is to wipe out the discharge at frequent intervals—a method which has been found to give results superior to any other. But in private or out-patient practice we want a method of treatment that does not depend on rigid asepsis and constant attention, and that can be applied by any moderately intelligent layman. Glycerin containing 2 per cent. phenol (the *B.P.* preparation is too caustic) used as hot as is comfortable has established its reputation as an "ear drop." It is excellent both before and after the onset of discharge, but it does not mix well with the latter, so that this must be carefully removed before use. The phenol is mildly analgesic: glycerin itself is a potent antiseptic, but its principal value is due to its hygroscopic action.

MAGNESIUM SULPHATE IN THE "DRY" TREATMENT

A hygroscopic application might be expected to promote drainage by reducing local congestion, and also to encourage a thinner and more watery discharge. It was with this object that I introduced magnesium sulphate as a dressing for the ear.[2] The essential of any "dry" treatment is thorough cleansing of the meatus, failing which applications lie inertly in the outer part, separated from the tympanum by a layer of discharge. It is worth a little trouble to learn, and to teach, how to make a suitable pencil of wool, for it is a pencil that is needed, not a spherical knob (Figs. 6 and 7). Take a thin, oblong piece of the best cotton-wool (no one can make a good mop with cheap fluff), about one inch by one and a half inches, and lay it on the left index finger. Place the end of the wool-carrier (a match or an orange stick) on it in line with the long axis, but projecting half an inch over the end (Fig. 8). With the left thumb fold the wool longitudinally round the carrier and, pressing thumb and finger together, rotate the carrier so that the wool becomes firmly attached to it. Maintain the pressure and rotation while the wool is withdrawn between finger and thumb, so as to form a uniformly thin cylinder; the free end is left fluffy, and not twisted into a point. Draw the ear out and a little back, and plunge the mop right down to the membrane and out again. If the discharge is sticky ten or twelve mops will be needed properly to cleanse the meatus. Half fill the meatus with powdered magnesium sulphate (crystals, *not* exsiccated), and cover it with a large piece of wool in the bowl of the concha. Where discharge is free, four-hourly treatment is needed, but in a day or two twice a day suffices.

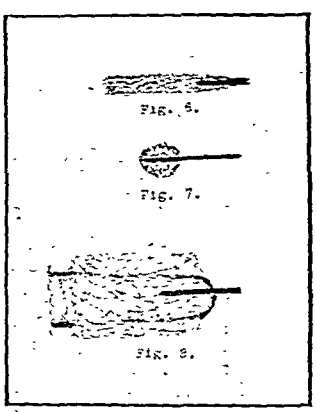

FIG. 6.—Section through good aural mop.
FIG. 7.—Section through bad aural mop.
FIG. 8.—Starting to make aural mop.

Since adopting this method two years ago the results, especially as regards hearing, have been so satisfactory that I now employ it as a routine. In chronic cases it is indicated wherever the discharge is free or gelatinous. But it is in acute and subacute cases that its value is best seen. During the recent influenza epidemic about half the cases of "acute mastoiditis" admitted to my wards for operation have recovered completely without this being required, and the method has been even more successful in private practice. As a rule the ear is dry in about three weeks, often less. If the hearing is not rapidly improving at this period it is a good plan to inflate the ear (with a Politzer bag) once or twice a week, though this is seldom necessary.

If the discharge has dwindled to a mere trace, but does not entirely cease, a more stimulating regime is desirable. Alcohol (90 per cent.) has long been employed. It is too painful for use during the acute stage, and many patients find it unpleasant even later. Iodoboric

powder* is satisfactory and well tolerated. It is used exactly as the magnesium sulphate, or applied by means of an insufflator, twice a week. One word of warning is needed. In adults with good hearing and old-standing, *minimal, inoffensive* discharge, it is sometimes best to rely on regular cleansing and not to attempt to obtain healing, since this may be achieved only at the expense of auditory function.

To treatment on these lines the response is usually rapid and satisfactory. Failure may be due to unsuspected nasal infection or to some general condition, such as debility, diabetes, syphilis, etc. Granulations ("polypi") must be removed before treatment can be effective: they are due occasionally to syphilis, but nearly always indicate osteitis. If, in a chronic case, the discharge continues offensive or frankly purulent despite six weeks of careful treatment, the cause is practically certain to be osteitis, as a rule with cholesteatoma. The question of operation should then be seriously considered. The risk of a grave complication, though not negligible, may be slight, but an enormous amount of chronic ill-health is directly due to persistent mastoid infection.[3] Almost invariably in these cases the acellular type of mastoid is found. On the other hand, one seldom has to operate for primary acute mastoiditis on persons (except infants) with acellular mastoids, probably because the aditus affords relatively good drainage for the small area beyond it. With material, old-standing deafness there is nearly always disease of the ossicles, and nothing short of the radical mastoid operation is effectual; but children show such great powers of recovery that the tympanum should be conserved unless manifestly seriously diseased.

In acute otitis media the need for operation may, of course, arise quite early, sometimes indeed before the onset of discharge. The general condition affords a better guide than local signs, pain, tenderness, or even oedema. Quite a number of "acute mastoids" recover completely without operation, though perhaps it is only after considerable experience that one can forecast the course of any given case. In influenzal otitis, when there is considerable deafness, the question of operation assumes early *importance*—I have seen irreparable damage to hearing within ten days of onset—but if four weeks from the start of any acute otitis the ear has not healed, or at least is not quite definitely healing, the decision as to operation must by no means be postponed. It is true that children often recover good hearing after many months of otorrhoea, but the proportion falls steadily month by month, and much more rapidly in adults. If the opposite ear is deaf there is an additional reason for urging early operation in the acute case. A week never passes but I see patients whose hearing has been sacrificed by a refusal promptly to recognize that meatal treatment is not in fact succeeding. The simple (Schwartze) mastoidectomy is a safe operation, and the functional results are extremely gratifying.[1] The ear is the organ of hearing, not a drainage tube for a diseased mastoid.

SUMMARY

1. Suppurative otitis media begins in early life, a large proportion during the first two years.

2. It is suggested that adenoids and teething catarrhs are symptoms of hypovitaminosis.

3. All wet meatal applications are condemned.

4. As long as discharge is free treatment should be careful removal of this, and application of powdered magnesium sulphate.

5. When discharge is less persistent a powder of iodine 1 part and boric acid 100 is recommended.

6. The importance of early operation as a means of saving hearing is emphasized.

* Iodine one part, boric acid 100; rub together into a fine powder and keep well stoppered, as the iodine is volatile. Not to be used after mercurochrome.

SOME NOTES ON INDUSTRIAL ANTHRAX

ITS DIAGNOSIS AND TREATMENT

BY

F. W. EURICH, M.D.ED.

HONORARY CONSULTING PHYSICIAN, ROYAL INFIRMARY, BRADFORD, AND FORMERLY BACTERIOLOGIST TO THE ANTHRAX INVESTIGATION BOARD OF BRADFORD AND DISTRICT

Bradford and district have the unenviable reputation of being the chief centre of industrial anthrax in this country. It was here that the name of "wool-sorter's disease" was coined, and "*maladie de Bradford*" is the name still given in France to pulmonary anthrax. This relative frequency of the disease in the West Riding and the courtesy of colleagues have enabled me to see and take notes of 340 cases of cutaneous anthrax and of twenty-four cases of pulmonary and gastro-intestinal anthrax.

SOURCE AND MODE OF INFECTION

The source of infection can in some cases be ascertained with certainty, as when a butcher contracts cutaneous anthrax from slaughtering a beast subsequently found to have suffered from splenic fever, or when anthrax bacilli have been cultivated from a sample of yarn previously handled by the patient. On another occasion anthrax bacilli were grown from both warp and weft handled by a patient, from the remainder of the raw material from which warp and weft had been spun, from portions of the same raw material bought by firms in two distant towns, and finally from clippings of cardigan jackets which had been made from the same material before its infectivity had been discovered. At other times the source of infection is left in doubt, either because the patient had been in contact with more than one species of dangerous wool or hair, or because the material handled by him had already been worked up and had left the factory by the time the investigation could be conducted.

The mode of infection, on the other hand, is often left in doubt. There can be none when the patient has, for example, been able to trace infection to a prick from the pin of a preparing machine through which infected mohair was found to have passed, or when a farm-hand with chapped hands and wrists had been detailed to assist a butcher, and subsequently presented five separate pustules, all of the same age, on these parts. In most cases the mode of entry cannot be determined. I have examined bacteriologically the scrapings from under the nails of all the workpeople employed in a factory from which cases of anthrax frequently reached me, without success. A schoolboy died of an anthrax pustule in the cheek: he had played football during the dinner-hour with some lads clad in the overalls worn by them while handling East Indian wool. While an abrasion here probably afforded an entry to the virus, there was no evidence as to its mode of entry in the case of a lad who died of a malignant pustule after sleeping on some sacking

which had contained Persian wool. Pimples are often claimed to be the point of entry, but it is difficult to see how they could be unless they had been injured and blood had been drawn. In many cases there is no history of a lesion of the skin, and it is supposed that the infecting spores may be passed mechanically along hairs to their roots, and thus initiate the "pustule." The clothes of workers may convey the infection: three women contracted the disease washing their husbands' overalls; and a wool-sorter who had been away from his work because of a broken arm died of pulmonary anthrax after a street fight, in which he had received a "dusting."

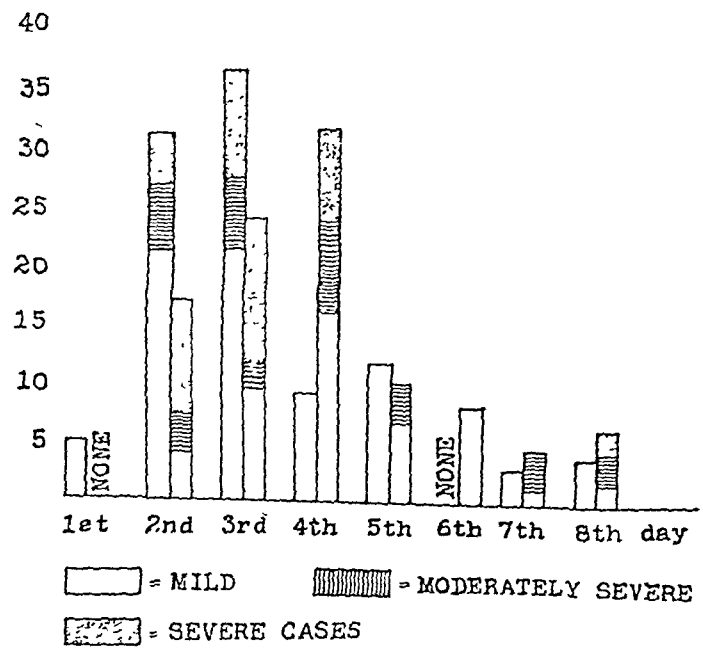
CUTANEOUS ANTHRAX

Cutaneous anthrax is naturally seen with greatest frequency on exposed parts, and of these some are more easily infected than others, the occupation being sometimes the determining factor—as in that of tanners, in whom, as a result of their mode of carrying the hides, the neck is a frequent site of the pustule. It is, however, a curious fact that the skin of the fingers is rarely attacked. On the other hand, I have seen "malignant pustules" on the shin, on the thigh, and even on the abdominal wall and between a woman's breasts.

The appearance of cutaneous anthrax varies. Its most common form, the "malignant pustule," is often said to be a characteristic structure when fully developed. This is an error. Given a vaccine pock on an unusual site, such as the angle of the mouth, the eyelid, or the cheek, accompanied as it often is in these situations by much redness and swelling of the surrounding parts, then mere inspection will fail to find distinguishing features. A history may help, as the vaccine pock takes somewhat longer to attain maturity: even this may deceive. The presence of a recently vaccinated member of the household may give our thoughts the right direction. The following case was more difficult. A lad employed upon dangerous wool had a "pustule" on the side of the neck; there was no one in the house who had been vaccinated. On closer questioning I discovered that the boy was wearing the clothes which his elder brother had discarded after having been vaccinated on joining the Army some weeks before. Streptococcal and pneumococcal infection of the skin may also produce lesions indistinguishable clinically from anthrax; this is true not only of the rare erysipelatous variety of anthrax, but of the "malignant pustule" also. I have once seen the hay bacillus give rise to a similar lesion. In other words, the diagnosis of cutaneous anthrax is primarily a bacteriological one. If this be applicable to the diagnosis of the mature classical "pustule," it is doubly so to the aberrant forms. Instead of the coal-black central eschar surrounded by a ring of vesicles upon an angry, red, and brawny base, we may find the eschar only without any vesicles, or the vesicles may be set some distance from the former; in other cases—and these are not necessarily early ones—bullae may predominate, a relatively small eschar lying among them; or one or two bullae may alone be present. In a fatal case of cutaneous anthrax of the wrist a white oedema replaced the red inflammatory area, and on it was one large flaccid bulla containing blood-stained serum. In another fatal case a similar white oedema disfigured a girl's chin and neck, but there was no vesicle or bulla, only a tiny black eschar, the size of a pin's head, on the point of the chin. In some instances the redness and inflammatory oedema may be almost absent, while in others it may involve a whole limb, or, extending over face, neck, and chest, give these parts gigantic proportions. If, then, a bacteriological examination is necessary for the diagnosis even of the fully developed lesion, it is more than ever necessary if the disease is to be recognized in its early stages, when most amenable to treatment. A spot not unlike a flea-bite in size, shape, and colour, crowned perhaps by a tiny vesicle or by a minute abrasion, may meet the disappointed view of the spectators of a demonstration; yet anthrax bacilli will have been found in the contents of the vesicle or in the serum obtained from the denuded area after gentle scraping with a scalpel. A further difficulty is introduced at times by the applications of homely remedies, such as cobbler's wax or poultices, which may profoundly alter the natural appearance of the lesion.

A few slides, a watery solution of methylene-blue, gentian-violet, or fuchsine, and a 1/6 inch objective are all that is needful. So rarely has the microscope failed us that it would be a mistake to postpone specific treatment until cultural confirmation shall have been obtained; but as anthrax is a disease to which the Workmen's Compensation Act applies such confirmation should always be sought. If the serum has to be sent to a distant laboratory it is best to dry some of it on threads, on slides, or on sterilized fragments of earthenware, and not to forward it in capillary tubes only, as the serum often possesses bactericidal properties. It is strange that relatively little constitutional disturbance may accompany extensive local changes, and this disproportion, though not characteristic of anthrax, is yet suggestive, especially in the erysipelatous variety, in which a "pustule" is absent.

ANTHRAX OF RESPIRATORY AND ALIMENTARY SYSTEMS



Thus, once the possibility of cutaneous anthrax occurs to the mind the diagnosis is generally easy—not so the diagnosis of anthrax of the respiratory system and of the alimentary tract. Of the latter I have seen only one case, in consultation with Dr. Marshall, late of Halifax, who had made the diagnosis by a microscopical examination of the blood-stained vomit. I have, however, seen two cases in which the stomach became infected secondarily, serum having trickled, from the nose in the one, and from the forehead in the other, into the mouth. The possibility of achlorhydria in these patients was unfortunately not considered. Three infections occurred in the upper respiratory tract—one affecting a nasal passage, a second the right tonsil, and the third the tissues between the epiglottis and the anterior pillar of the fauces: only the first case survived. The twenty-three pulmonary cases all ended fatally. In one the diagnosis was made reasonably early by use of the opsonic index, while in a second the disease was strongly suspected on clinical grounds. The diagnostic history of the remaining twenty-one cases was as follows: in four cases no medical advice was sought; in eight the patients were dying when advice was sought; in four suspicion was aroused only by sudden and unexpected death; in five no suspicion was aroused till collapse occurred. Though this shows how rarely an opportunity is given for considering the possibility of internal anthrax at an early stage, and how ambiguous and relatively innocent the initial symptoms may be, yet occasionally the constellation of the symptoms is so unusual as to call for special consideration, as when joint pains and precordial oppression, or joint pains and glandular enlargement, are complained of. It is conceivable that when suspicion has been aroused the estimation of the opsonic index, or the bacteriological examination of blood drawn from the affected lung, may confirm it. The examination of a pleural effusion will rarely benefit the patient, as these effusions are usually of late occurrence; nor will the examination of cerebro-spinal fluid when there is cerebral involvement. Recovery from internal anthrax is very rare. I find no record of such recovery in the clinical notes left by the late Dr. J. H. Bell, nor have I seen one. The late Dr. Wm. Mitchell of this city published notes of one alleged case of

recovery, but the diagnosis had not been confirmed bacteriologically.

The generalization of anthrax is largely embolic, as is shown by the distribution and structure of the secondary intestinal lesions, the emboli being derived from thrombosed veins in the area of the primary focus. It is very doubtful whether the bacilli multiply in the blood stream. Their presence in it is not necessarily a sign of impending death. I have on several occasions been able to cultivate them from the blood, and yet the patients recovered. A sign of ill omen is delirium. Consciousness to the last is a characteristic of anthrax. Often the patient feels the approach of death: "I am done for" is a common expression, but now and again this feeling is absent. "How do you feel?" a dying patient was asked, as he lay pulseless: "Oh, nicely, only a bit weak," he replied, turned on to his side, and died. On another occasion the anxious family doctor called upon his dying patient at 1 a.m., expecting to find the family about the bed. To his surprise the house was in darkness: all had gone to bed and were vexed—the patient included—at being disturbed "without reason"; the man died four hours later. Delirium almost always indicates involvement—haemorrhagic in nature—of the meninges; this pia-arachnoid haemorrhage is often so extensive as to cover the whole brain and even to extend to the coverings of the cord.

PROGNOSIS

The prognosis of anthrax, and especially of the cutaneous variety, depends largely on an early diagnosis. This is best ensured by the appointment in centres in which industrial anthrax is known to occur of a medical practitioner whose duty it shall be to examine every operative presenting suspicious symptoms. To this end the Factory Department of the Home Office has issued an illustrated monitory poster to be hung up in the factories and workshops. This plan has been adopted in Bradford, and its results are shown in the accompanying diagram,

The first of each group consists of patients first seen by specially appointed practitioners; the second of each group consists of patients first seen by other practitioners.

in which mild, moderately severe, and severe cases are arranged according to the day of the disease on which the diagnosis was made, and as to whether seen by a general practitioner or by the appointed examiner. The advantage of the system is obvious. The comparison thus made is a fair one, as all the patients were treated in the same institution and on the same principles.

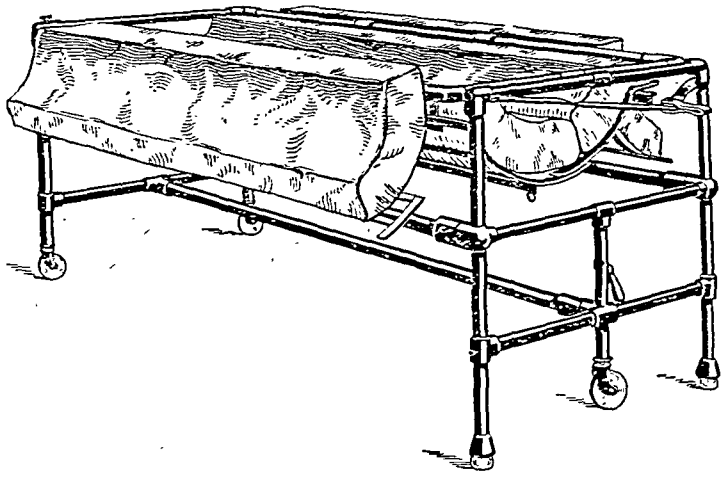
TREATMENT

The treatment of cutaneous anthrax used to be excision whenever the site of the "pustule" permitted. We have now for many years discarded excision, reserving it for those cases in which the "pustule" is very small and on a site notoriously apt to favour rapid extension, such as the neck. Excision is still claimed by some to be the safer method, the accidental entry of bacilli into the operation wound being considered of no moment. It is true that successful infection depends upon the number of germs introduced into the tissues. That number may on occasion be so small as not to be dangerous, but the veins beneath the "pustule" are often extensively thrombosed, the thrombi crowded with bacilli, and I have seen disastrous results follow their section. With the abandonment of excision as a routine method of treatment our results have improved, the mortality of the last 200 cases of cutaneous anthrax being only 5 per cent. It is not possible to compare these results with those obtained by others: their figures are often too small, and prognosis depends so much upon factors not referred to in their statistics, such as the frequency with which certain sites have been affected, the stage in which treatment was begun, and the nature of the infecting material. It is obvious, for instance, that statistics which include many cases of pustules on the neck cannot be justly compared with those in which most of the lesions have occupied less dangerous sites. When excision is decided upon, the greatest possible care must be taken to avoid infection of the wound. A rise in temperature a day or two after the operation may indicate its occurrence; but fever is not a necessary accompaniment. At the Bradford Royal Infirmary excision has now been replaced in most cases by the injection of salvarsan and of anti-anthrax serum. Since 1911 it has been my practice whenever I have used salvarsan to give two moderately large doses, the size of the dose being relative to the sex, age, and constitution of the patient, generally with an interval of a day. It is rarely necessary to give more, and I have never deemed it desirable to give—as I have heard have been given elsewhere—daily injections of some magnitude for a whole week. With no other treatment but this I have seen fever subside rapidly, with a coincident general improvement; but we usually combine it with the older method of injecting, intravenously or subcutaneously, anti-anthrax serum.

First introduced in 1899 Sclavo's serum has been almost solely employed. The results attending its administration appear to us to have been so good that the use of other serums seemed scarcely justifiable. Only during the war, when Sclavo's serum was for a time unobtainable, did we employ Mulford's serum, with success in the few cases in which it was given. The initial dose of either serum has since 1908 been 80 c.cm., followed by 60 c.cm. on the following day. Sometimes the dose of 80 c.cm. was repeated, and injections up to a total of 300 c.cm. have been given with no ill effects other than the usual joint pains and urticarial eruptions. The relative values of these remedies are uncertain; salvarsan, however, offers the advantage of being easily obtainable. Whichever method of treatment is chosen, one condition must in every case be fulfilled: the part affected *must* be put at rest. The necessity of this was brought home to me many years ago by the relative mortality of patients with malignant pustules on the wrist and on the forearm: of eleven with pustules on the wrist seven died; and of a similar number with pustules on the forearm, none. The greater mobility of the former is the obvious explanation. If a limb is the site, it is carefully splinted, and if an arm, it is also supported on a pillow. If the head or neck is affected,

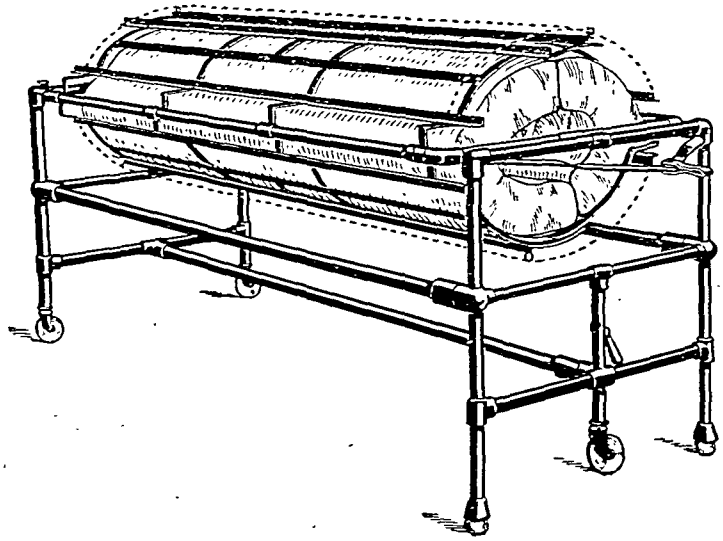
then sandbags are applied and the head is kept in position by a folded towel carried across the forehead and fixed beneath the sandbags.

The internal administration of sulphur has been advised; with what justification based upon experience I know not. I have used chrom-argentum in one case, which ended in recovery; it has been claimed that very severe cases have been cured by the sole administration of it intravenously. In China (Hankow), I am told by Dr. E. F. Wills, certain leaves are credited with curative properties, and samples have reached me; but as only two authenticated cases have, to my knowledge, been so treated—with recovery, it is true—I have not felt justified in applying the leaves to the exclusion of every other remedy—the only method by which their claim to utility can be vindicated.



AN IMPROVED PATTERN OF THE REVOLVING SPINAL BED

BY



ERNEST W. HEY GROVES, M.S., F.R.C.S.

EMERITUS PROFESSOR OF SURGERY, BRISTOL

Three years ago I published an account of a special reversible spinal bed (*Journal*, January 11th, 1930). Since that time the value and utility of this appliance has been abundantly demonstrated by the experience of others as well as myself. But a difficulty in its use has also been experienced, and this has been overcome by the design of a new model.

The principle of the bed is to enclose the patient in a cage, which, supported on a bed-frame, could be revolved. When the patient is lying on his back the front of the cage can be removed, and when he has been turned over the back can be exposed by removing the back part of the cage. In the original model the cage was flat behind and in front—that is, it was shaped like a parallelogram in transverse section. The difficulties met with in the use of this pattern were twofold. First, it was necessary to pack the patient very tightly in the cage by a number of pillows, in order to prevent him from slipping sideways in the act of turning him over. Secondly, it was difficult to adapt the same cage for thin or stout patients, and this, too, could only be done by packing with pillows in the case of a small patient.

The new model illustrated here overcomes both these difficulties. The cage is oval or elliptical in transverse section. The patient lies in a trough, formed by a shaped mattress, in two halves, lying on the curved framework of the cage. This has another advantage, in addition to the firmer fixation, when being turned. It is that the patient's body is kept more rigid when lying on his back in this trough than it was when he lay on a flat mattress: he cannot roll from side to side, and this prevention of rolling is certainly desirable in cases of spinal affections, whether tuberculous or traumatic. The front of the cage is also curved in transverse section, and this is more easily explained by reference to the illustration than by description. In the upper figure the cage is open, the front portion being thrown back and lying against the sides of the bed. In the lower figure the cage is shut, as it would be when the patient is about to be turned over. In this position the patient lies held quite snugly all round his body and legs by the mattresses, and there is no need for any packing pillows. When he is being turned he is held just as securely when half-way round, on his side, as he is when lying on his face, or on his back, so that the turning can be done as slowly as desired. The oval shape of the frame makes it easy to adapt it to patients of different girth. The curved metal bars of the frame overlap for rather more than six inches, and can be locked in any one of six different positions, so that as this varying amount of overlap occurs behind as well as in front, the circumference of the oval frame can be varied by 12 inches. The arrangement of the bedpan may be made in one of two ways. There is a gap between the back mattresses opposite to the buttocks. This can be occupied by a round cushion or the bedpan, or, if the patient is incontinent, or if a nurse is not in constant attendance, the bedpan is placed outside the cage supported on a special metal arm, which can be swung into place or outwards as may be desired.

I have found this type of bed-frame of the utmost service for all kinds of serious spinal disease, and especially for those necessitating bone grafting or laminectomy. Then, too, fractures of the spine, with or without paraplegia, almost demand some such appliance. The back, the buttocks, and the skin require daily attention to prevent bed-sores, and it is almost impossible to move such a patient without great risk and great pain, unless

some mechanical device is provided. With this bed one nurse can manage the case single-handed without effort or strain. With the ordinary hospital bed a patient with a fractured spine can only be turned by the united efforts of two, three, or four nurses, and each turning movement is painful and risky. In addition to cases of spinal disease or injury, those of fractured pelvis are most conveniently treated on this bed. The pelvis and buttocks are firmly held when the patient is turned over.

The bed is made by Messrs. Nesbit Evans of Wednesbury, and can be obtained from Messrs. Down Bros., 21, St. Thomas Street, S.E.1.

THE PERMEABILITY OF THE BODY TO INFRA-RED RAYS

PRELIMINARY COMMUNICATION

BY

C. B. HEALD, M.D.

PHYSICIAN IN CHARGE OF THE PHYSICAL MEDICINE DEPARTMENT, ROYAL FREE HOSPITAL

It is impossible to work with the Finsen light on lupus, or with the Kromayer lamp on tuberculous or other glands, without being convinced that clinically these apparatuses behave quite differently when compared with any of the ordinary methods of giving ultra-violet light to the body. The Kromayer lamp is essentially a mercury vapour lamp, and even when care is taken that the dose, as judged by skin erythema, is the same, the mechanical and physical differences between these two lamps are significant. In the Kromayer the rays emitted from the mercury arc travel through a very small air space, then through a circulating body of cold water; they then pass through quartz direct to the part to be treated, which is rendered as far as possible avascular by pressure. In the ordinary mercury vapour lamp the rays emitted pass through a relatively wide air gap before reaching the skin. The clinical differences observed must therefore be due either to the absorption of some ray in the air in the one case, to the removal of some other ray or rays by the water in the other, or to the greater permeability to some useful ray possessed by quartz and water in comparison with air.

Some three years ago Professor T. R. Merton kindly gave me the benefit of his technical advice on these observations, and pointed out that the water film cuts off all rays above about 11,000 Angström units, but that in the mercury vapour arc there is a strong band of infra-red rays between 7,000 and 9,000 units, and that it might be this band that accounted for the clinical differences, particularly in tissues below the skin. He supplied a filter that cut off the ultra-violet part of the beam, and experiments with this showed that his surmise was correct, and that reduction in glandular swellings could be effected without the production of the skin erythema associated with ultra-violet light irradiation. The drawback to the routine use of this filter lay in the fact that, while eliminating the ultra-violet, it also reduced the energy of the infra-red beam, and necessitated a greatly prolonged dose to produce adequate clinical response.

The production by the *Times* of their wonderful series of infra-red photographs reawakened my interest as to the possibility of using a similar process for taking photographs through the body, in the hope that, if successful, the rays would be found to penetrate tissues in a different ratio to *x* rays, and to show up structures not well delineated by the latter. They would thus form a complementary method for giving information about the internal condition of the body, particularly the soft tissues in and around joints.

PRELIMINARY INVESTIGATIONS

That rays towards the red end of the spectrum pass more readily through skin tissues is, of course, known to everyone who has held his hand to the bright sun and seen the pink appearance of the fingers. Carl Sonne[1] and Cartwright[2] have discussed the penetration of infra-red rays, and the latter, using a vacuum thermo-couple, took photographs of the spectrum on infra-red plates after passing a beam of light through the cheek. The diagnostic possibilities of the permeability of tissues to the infra-red rays do not, however, appear to have received attention, nor can any attempts be traced in the literature towards making these rays penetrate and emerge from the thicker parts of the body, and registering them on emergence.

With my experience of the Kromayer lamp, and the *Times* photographs in mind, I approached Mr. Bloch, Mr. Flower, and Dr. Harrison of Ilford Limited, who kindly endeavoured to obtain photographs through the hand, and, though these showed clearly that infra-red rays did go through the thickness of the fingers, the comparative insensitivity of the plates as at present manufactured so prolonged exposures that they made the method impracticable, even for such thin structures as the fingers, and quite impossible for the thicker parts of the body. I therefore asked Mr. Bloch if he would attempt to pick up the emergent ray on a photo-electric cell, and demonstrate its presence by a deflection, if any, on a suitable galvanometer. A diagram of the apparatus set up by Ilford Limited for picking up the emergent ray is illustrated in Fig. 1. It will be seen to consist simply of

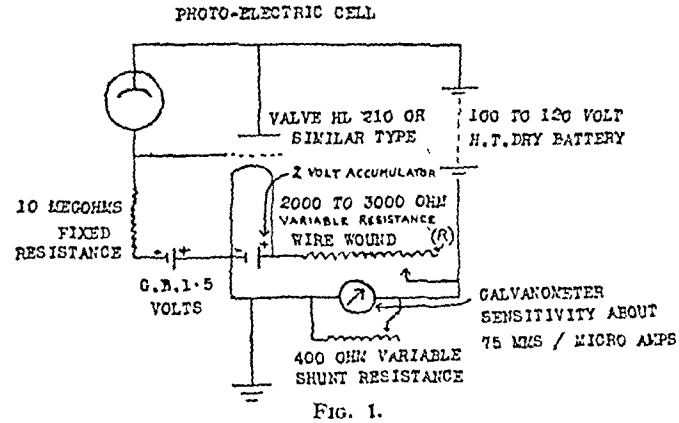


FIG. 1.

a photo-electric cell particularly sensitive in the region of 7,000 to 9,000 Angström units, and a single-valve method of amplifying any alteration in the current flowing in the filament-plate circuit, such alterations being indicated by deflections on the galvanometer inserted in this circuit.

TECHNIQUE AND RESULTS

It then only remained to provide a source of infra-red light in such a position that the beam would fall upon the photo-electric cell. This was done by an ordinary 50-watt or 100-watt lamp in a light-proof casing with an infra-red filter upon the side facing the photo-electric cell. The cell was also encased in a light-proof metal shield, with aperture to admit the incident beam. The gap between the filter and the shielded cell was sufficient to admit a wrist or forearm, and also a movable screen opaque to infra-red rays. In the preliminary investigation a reflecting galvanometer was used, and the experiments were carried out in a dark room, so that stray beams of light should not be reflected off the skin and produce misleading deflections. These experiments showed that, with appropriate sensitivity in the amplifying instrument, a wide deflection of the spot of light could be obtained after the infra-red beam had been passed through

a wrist. The next step was to endeavour to obtain a permanent record of the deflection so that variations in normals and abnormals could be measured and possibly standardized. The electrocardiograph galvanometer and recording camera appeared to provide the possibility of doing this, and the leads for the galvanometer were carried to a pair of Einthoven leads of a standard Cambridge instrument apparatus kindly loaned by Dr. Jenner Hoskin. The procedure was then to put the fibre at a prearranged position on the scale, with the infra-red opaque screen in place, and turn on the source of infra-red light to make sure that no deflection occurred. The wrist or forearm was then interposed and closely applied to the infra-red filter, so that all rays emerging through the filter were bound to fall upon the skin and skin only. The screen was then withdrawn, and the string of the galvanometer at once deflected and returned to its original position on replacing the screen. Photographs of this deflection were then taken by allowing the plate to fall in the usual way, removing the screen, and replacing it a few times as the plate fell.

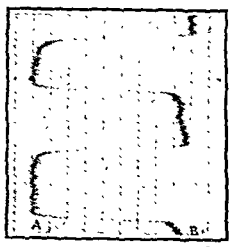

FIG. 2.—H., male, aged 50. Left wrist-joint, with centre of beam between styloid processes.

The accompanying graphs from three different individuals (wrists and forearms) with the same setting of the machine were then secured. It is not possible to state at this stage that the wide variations shown by these graphs are due entirely to differences in the permeability of the structures through which the rays pass. It is only possible to state that repeat experiments yielded similar results. In the illustrations A indicates the position of the fibre with the screen inserted; B indicates the position with screen withdrawn.

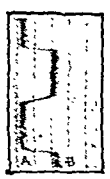

FIG. 3.

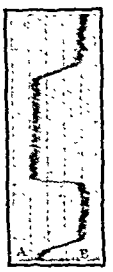

FIG. 4.

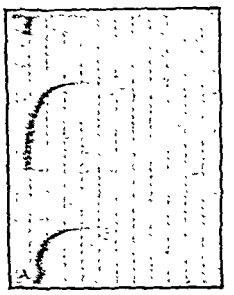

FIG. 5.

FIG. 3.—M., male, aged 30. Wrist-joint, with centre of beam between styloid processes. Transverse diameter of this wrist was 3 mm. more than in Fig. 2.

FIG. 4.—M., male, aged 30. Right forearm, a few inches above wrist-joint.

FIG. 5.—H., male, aged 21. Left wrist-joint, with centre of beam between styloid processes. In this case the subject is of altogether more slender build than either of the other two cases. The deflection of the fibre is so great that the "B" position is unknown, being off the plate.

DISCUSSION

These photographs can therefore be taken to establish the fact that infra-red rays of 7,000 to 9,000 Angström units can pass completely through the wrist and forearm. Also, as the source of energy was limited to a 100-watt lamp, and the sensitivity of the string of the galvanometer was only 3 mm. for 3 millivolts—that is, one-tenth of the sensitivity used in taking heart tracings—that, with greater incident energy and increased sensitivity of the galvanometer, thicker parts of the body than the forearm should be capable of penetration and the deflection of recording.

This preliminary communication is made in the hope that others will explore the wide field opened up by these records. Questions such as the following naturally occur:

1. Is there a "normal" for parts of a given diameter?
2. What factors influence variations from the normal other than physical thickness of the part—for example, age, sex, etc.?
3. Is there any variation in disease? For example, does an arthritis of one wrist produce a deflection different from that obtained by the wrist of the other side?
4. With increasing power and sensitivity of recording, what are the limits of thickness of the body to the passage of the infra-red ray?
5. Can anything be done to increase the speed and sensitivity of plates and films sensitive to these rays, and thereby obtain direct photographs?

Other questions also naturally suggest themselves, but I am endeavouring more particularly to obtain further information on Questions 1 and 4.

It would not be appropriate to close this communication without again extending my grateful thanks to Messrs. Ilford and their technical staff, Mr. Bloch, Dr. Harrison, and Mr. Flower; to Dr. Jenner Hoskin; and last, but not least, to Mr. Holt, whose technical knowledge and skill has materially assisted in obtaining these records.

RADIUM BURNS

BY
J. MERVYN THOMAS, M.D., B.CH., B.Sc.
RADIUM REGISTRAR, CARDIFF ROYAL INFIRMARY

The incidence of radium burns during or following surface radiotherapy by the plaque method is not often mentioned when quoting cases, but it must, of necessity, be proportionately high where a biological unit of radium exposure has not been attained. With the object of helping the radiotherapist, therefore, the following brief account has been compiled.

No statement would be adequate unless some clinical method for calculating the dosage were stated. It has been found that the skin undergoes certain changes during irradiation, beginning with an erythema towards the third day, and passing through an oedematous stage to tissue necrosis somewhere about the sixth to tenth day. The oedematous stage should be the aim of the therapist during treatment; it occurs rapidly in the course of twenty-four hours. All treatment should then cease, as the skin has reached its limit of tolerance. When this simple rule is applied the skin rarely ulcerates.

The caustic action of the β ray is too often neglected during treatment. The β ray is not tolerated nearly so well by normal tissues, and destruction must follow when the areas are exposed to high intensities for short periods or to low intensities for long periods. The burn may be immediate or latent. If the former, it develops during treatment or at any time up to three months, and may vary in form from a simple erythema to desquamating patches and finally definite ulceration. Later these may become excavated areas with a yellowish grey slough and persistent discharge (purulent or watery). Pain is usually severe and healing obstinate. The delayed burn occurs any time after three to six months, and is manifest by an ulceration of the skin following some irritation or friction.

PREVENTION AND TREATMENT

The following details have been tabulated for clearness:

1. Radium treatment should not be given to patients suffering from cachexia, anaemia, a white cell count under 5,000 per c.mm., diabetes, nephritis, extreme obesity,

Mr. A. J. WRIGLEY dealt with the management of uterine inertia in the second stage of labour. He emphasized that cases in which uterine exhaustion was secondary to a mechanical obstruction were not to be considered in the discussion; for the common type of delay due to muscular resistance he unhesitatingly recommended the application of light forceps to the foetal head. He considered that it was quite unnecessary to await the onset of maternal or foetal distress before the light forceps were applied. He demonstrated to the meeting the forceps which he used, which weighed 11 oz. instead of the customary 2 lb. He wished the meeting to consider whether it would not be better for teachers of obstetrics to advocate the more frequent use of short, light forceps in the treatment of inertia in the second stage than to teach the strictly limited use of the orthodox heavy instrument, which was far too clumsy and bulky for this purpose.

Miss BEATRICE TURNER described the management of the third stage of labour as practised in the Obstetric Unit of the Royal Free Hospital. No drugs, such as pituitrin or ergot, were ever given before the placenta had been expelled. She had attempted to analyse the causes which had produced prolongation of the third stage in a series of 400 labour cases. In her series, third-stage inertia was present in 65 per cent. of cases in which forceps were used. Analgesic drugs given in the first stage seemed to have had little effect on the expulsion of the placenta, but the anaesthetic used for the second stage had a definite effect. Gas and oxygen seemed to improve the tone of the uterine muscle, and hastened the delivery of the afterbirth. Chloroform, on the other hand, had been found to result in delay.

GENERAL DISCUSSION

Dr. J. M. WYATT was against using hyoscine and morphine in large quantities, and thought that equally good results could be obtained by giving chloral, but it must be in sufficient doses. Twenty-grain doses were not sufficient—they should be 40 grains at least, or, as an alternative, paraldehyde, 6 or 7 drachms in olive oil, could be given per rectum with good results. In cases with ruptured membranes, with the foetus alive, he had found Willett's forceps applied to the scalp of the foetus the most useful instrument. He had one comment to make on Mr. Bell's statement that if the membranes had ruptured the risk of Caesarean section was greater: he felt that it came about from the fact that, in so many cases where the membranes had ruptured, much manipulation had taken place, whereas if no internal examinations had been made there was no greater risk to the patient. For the last fifteen years he had invariably given 5 units of pituitrin as soon as the baby's head was born. During that time he had never had a retained placenta, and he had found that the third stage of labour usually lasted only five minutes, and that very little blood was lost.

Mr. CARNAC RIVETT said that he was an advocate of the administration of small doses of chloroform, given only during pains, but he wished to state that in primary inertia he considered this form of relief absolutely contra-indicated.

Dr. J. S. FAIRBAIRN congratulated the openers on their papers. He considered that the only logical method of treating uterine inertia was to prevent it or to adopt measures which would have the effect of restoring normal function. He felt that there was a great deal to learn on this subject. Mr. GORDON LUKER considered that uterine inertia was to some extent preventable, and that prophylactic treatment had an important place. In his practice this treatment consisted in the administration of calcium and quinine for the last three weeks of pregnancy, and the employment at term of castor oil, a binder, hot bath, an enema, quinine, and bihydrochloride. The speaker had no doubt about their efficacy. He agreed with the use of pituitary extract at the end of the second stage of labour. His method was to give 1/2 c.cm. of pituitary extract before resorting to forceps. If the drug did not act successfully delivery was aided by forceps without delay.

In reply, Mr. A. C. BELL said that his advocacy of pituitary extract in the first stage of labour had been questioned. He had seen dramatic results from giving it in inertia; it could do no harm in doses of 1/2 c.cm. He wished to refer to one further point: it had been claimed that atropine would relax the rigid cervix. He considered that there was no foundation for that statement. Mr. Marshall, referring to Mr. Wyatt's doubt with regard to the importance of the ruptured membranes, said he did not consider it was right to say that premature rupture of the membranes did not increase morbidity following Caesarean section, but he was certain that the lower segment Caesarean operation definitely minimized the risk. Mr. MALIPHANT said that he had not had time to mention in his opening paper the subject of heredity in connexion with protracted labour. He knew of families in which childbirth was always unduly tedious and painful. Mr. NEWTON said that he looked with apprehension on early rupture of the membrane in primigravidae. In 150 cases where the membranes were not ruptured early he never had to interfere, but in sixty cases in which there was nothing wrong except early rupture, he had had to interfere in 6 or 10 per cent. of them. Artificial dilatation of the cervix made a big difference in foetal mortality and maternal morbidity. Mr. WRIGLEY, referring to the use of the light forceps, said that he had not meant to imply that the long curved forceps should be thrown out of use, but that that instrument should be used only by those who were experts in obstetrics. It was not adapted for being used indiscriminately for high head or low head.

THE ANAEMIAS

The present state of knowledge in regard to the anaemias was reviewed at the summer meeting of the Association of Clinical Pathologists, held in the pathological department of Ancoats Hospital, Manchester, on June 24th.

Papers were read dealing with pernicious anaemia, anaemia of the so-called secondary types, and the anaemia of sprue, and evidence was produced that, thanks to the advance in knowledge in the last few years, all these anaemias were now definitely remediable. It was agreed that in the case of pernicious anaemia it was perhaps incorrect to speak of "cure," and the same applied, though to a lesser extent, in the case of some of the "secondary" anaemias, but in all it was now possible, once a correct diagnosis had been made, to restore the patient to health, and under suitable treatment to maintain him there. It was pointed out that correct diagnosis was an essential preliminary to correct treatment, and that this could only be made by the employment of laboratory methods. In the discussion attention was drawn to the deplorable wastage resulting from failure in correct diagnosis and inefficient treatment. This wastage involved material in the prescription of expensive preparations, particularly of liver, to unsuitable cases, and in the use of highly priced commercial preparations of low potency, evidence being produced that the most highly priced preparations were by no means the most efficient; it involved human efficiency in the persistence of many individuals in a state of debility who, with proper treatment, might be in good health; and it involved human life from failure of correct diagnosis and inappropriate and inefficient treatment. It was pointed out that the National Health Insurance Acts were largely ineffective in remedying this wastage, owing to the fact that they provided for treatment only and made no provision for diagnosis or for the laboratory examinations necessary for the maintenance of health in cases of anaemia. At the conclusion of the meeting the following resolution was passed:

This association is of the opinion that the failure to provide laboratory facilities for the examination of the blood in the case of patients under the National Health Insurance Acts suffering from, or suspected to suffer from, anaemia is responsible for much wastage both of material and of human efficiency and life, and considers that centres should be established at which such laboratory service be available both for initial differential diagnosis and for the periodical examinations necessary to assure the maintenance of a sound state of health.

Reviews

DISEASES OF INFANCY AND CHILDHOOD

An important and ambitious contribution to the literature of paediatrics has just appeared in the form of a two-volume textbook, *entitled Diseases of Infancy and Childhood*,[1] edited by Professors LEONARD G. PARSONS and SEYMOUR BARLING. The Birmingham school of paediatrics can justly be proud of this production, to which there are nearly fifty contributors, including sixteen or so who have some connexion with London and six from either Canada or the United States. It is difficult to judge exactly what criteria have led the editors to choose their helpers in every instance, and the omission of some names from the list, such as those of Still, Hutchison, and Fairbank, will be disappointing to many readers at home and abroad. To have secured Edwards A. Park and Martha M. Elliot to contribute the section on rickets has resulted in a magnificent article marred only by the number of black babies chosen for illustrations which are scarcely typical of what is to be seen in this country. On the other hand, it is difficult to judge why it was considered necessary to go to Canada for the section on the premature child, which, excellent as it is, could have been done equally well by J. C. Spence, who has written in the preceding pages on the neo-natal period in a masterly manner. The introductory sections on heredity (by E. A. Cockayne), growth and development, peculiarities of disease in childhood and clinical methods in paediatrics (by A. G. Maitland-Jones), and on the care and management of the infant and child (by K. Tallerman and A. Rose), are all very well done, while contributions on the State and child (by G. A. Auden) and on infantile mortality (by E. W. Hope and R. E. Bell) strike a useful note to remind readers of the wider implications of paediatrics. In about seventy pages Dr. Tallerman has packed an amazing amount of information on infant nutrition, which is dealt with on modern lines and could scarcely be bettered. Dr. Reginald Miller writes on rheumatism, and it is excellent to have this expert's views collected and presented in his own well-known style. The diseases of the blood and blood-forming organs are authoritatively dealt with by Sir Humphry Rolleston, and no doubt the Birmingham school will seek to enlarge and modify some of this in subsequent editions in light of the recent work conducted there. The disorders of the ductless glands are well described and illustrated, but the picture of a cretin at the age of 3 should be replaced by that of an infantile sufferer, since it is at this younger age so important to recognize the condition if full cure is to be achieved. Volume ii (in addition to the section on the blood already mentioned) is largely taken up with sections on the respiratory, cardiovascular, genito-urinary, and nervous systems. These are adequately dealt with, and the congenital disorders of the heart are made much clearer than usual by K. D. Wilkinson's intelligible descriptions and illustrations supplied by Maude Abbott. The surgical disorders of childhood are dealt with in close conjunction with the medical diseases with which they are associated, and the surgical editor is to be especially congratulated on the skill with which this has been carried out and on the broad outlook thus obtained. Only a few of the authors and sections have been mentioned here, and this must not be taken to mean that others are less worthy of notice. In particular, the contributions by Professor Parsons himself are of that clear and admirable quality which is to be expected from him. On coeliac disease he is thoroughly at home, and has produced a scholarly monograph in a dozen pages. To sum up, it may be said that if a new textbook of paediatrics is really required there could scarcely be a better production. The index, running to nearly ninety pages, is excellent, the illustrations throughout are well produced, and a radiographic appendix contains a series of good photographs. As works of reference, especially in view of a bibliography at the end of each section, these two volumes will be found very valuable.

[1] *Diseases of Infancy and Childhood.* Edited by L. G. Parsons, M.D., F.R.C.P., and Seymour Barling, C.M.G., F.R.C.S. Two volumes Oxford Medical Publications. London: H. Milford, Oxford University Press. 1933. (Pp. xxxvii + 1,798; illustrated. £4 4s. the two volumes.)

The appearance of a tenth edition of *Holt's Diseases of Infancy and Childhood*,[2] revised by Dr. L. EMMETT HOLT, jun., and Dr. RUSTIN MCINTOSH, challenges comparison with the new work, and from this it emerges very well. The two new authors are to be congratulated on the skill with which they have retained so much of the valuable original matter while including so much modern material. Here also an extensive bibliography renders the book a most useful work of reference, and the Johns Hopkins school of paediatrics has a worthy successor to the original authors (Holt and Howland) in the person of Edwards A. Park, who, it is stated, has read over and criticized much of the present edition. It contains much new work, and especially on disorders of nutrition and diseases of the blood and of the nervous system it is thoroughly up to date. Dr. Emmett Holt, jun., has performed his filial task in a manner which will maintain the great reputation his father's book has won.

PATHOLOGICAL ANATOMY

The tendency of modern writers is to combine the two subjects of pathological anatomy and pathological physiology; many of the later textbooks of pathology have this character. There is still room, however, for works in which the anatomical standpoint is adhered to according to the old model, and Sternberg's Pathology[3] is one of the best examples of this type. The work is a direct descendant of Birch-Hirschfeld's textbook; this was recast by Ribbert about twenty years ago, and the revised book was immediately recognized as one of outstanding merit, and has since always been referred to as "Ribbert's Pathology." It maintained its position for many years without revision, but latterly was in danger of falling out of circulation. It was felt by the publishers that this would be a matter for regret, and accordingly they approached Professor Sternberg with a view to the issue of a new edition. Professor Sternberg undertook the revision, which he completed in 1927. He found it necessary to rewrite much of the material, but an endeavour was made to preserve the general plan and character of Ribbert's work unaltered. The book at once resumed its position as one of the leading textbooks on the subject, and a second edition has now been called for. In this, Professor Sternberg has brought the subject up to date and has added a large number of illustrations, many of which are photographs of unusual excellence. At the same time the general features of Ribbert's book have still been retained as far as possible, and readers of Ribbert will be familiar with many of the illustrations of the original work.

Textbooks on pathological anatomy exhibit a close family likeness, and it is often difficult to point out in what particulars an individual work differs from its

[2] *Holt's Diseases of Infancy and Childhood.* By the late L. Emmett Holt, M.D., and J. Howland, M.D. Revised by L. Emmett Holt, jun., M.D., and Rustin McIntosh, M.D. Tenth edition. London and New York: D. Appleton and Co. 1933. (Pp. xix + 1,240; 205 figures. 42s. net.)

[3] *Lehrbuch der Allgemeinen Pathologie und der Pathologischen Anatomie.* Zweite, vollstandig umgearbeitete auflage. Von Dr. C. Sternberg. Begrundet von Professor H. Ribbert. Berlin: J. Springer. 1933. (Pp. 650; 759 figures. RM 38; Geb., RM 39.80.)

contemporaries, and what are its particular claims. This appears to have been felt by the author, for he states in his preface that he had some doubt, considering the number of published works on the subject, whether another was required. Sternberg's Pathology is, however, a serviceable book. It is very complete and accurate as regards the information it contains, has the advantage of being of moderate size, and is written in a manner which renders the subject-matter readily assimilable. The descriptions are direct and concise, and free from discursiveness; they leave a vivid impression, and essential features are readily grasped. On the theoretical side also the author shows great judgement; here again essential points are clearly and briefly indicated, to the exclusion of all that is of doubtful value. The publishers have done well to revive this standard and authoritative work.

CRIME AND THE STATE

Penal reform has made strides during the last quarter of a century; there are even signs that its advance has been in some ways rather more rapid than is altogether desirable. Fewer people have been sent to prison, sentences have been shorter, and the conditions of imprisonment have been much improved. Probation has been increasingly used, especially for young offenders. On the other hand, public interest of recent years has been focused more and more closely on crime, and the impression has grown up that crime is far more prevalent than it really is. For this state of affairs it is impossible for the Press to escape responsibility. The popular newspapers make much of their profit out of reporting crime news in a sensational manner, and it is largely due to this immoral practice that crime has become romanticized and over-emphasized. As E. R. and T. CALVERT show in their interesting study,[4] the increase is far less in numbers than in popular interest. Unfortunately, there is a tendency to blame the reforms of this century for such increase in crime as there has been, and to complain that the treatment of crime has lost its deterrent effect. The task of penal reform is most complicated and heart-breaking, and the reformer probably meets more determined opposition than he would in any other field. The Calverts have attempted to examine the whole question critically in order to permit a clearer understanding of the problem. They have written their book in a live and interesting way. Books on reform are interesting in proportion to their content of facts as against theories and opinions, and the fact-content of this volume is exceptionally high. It is no small achievement to be able to compress into three hundred pages of large, clear type a survey of the reasons for punishment in general and of the present state of crime and criminal procedure, a critical essay on the prison system, and a marshalling of the chief arguments against corporal punishment and the death sentence. The Calverts conclude that the present system offends in many ways against science, reason, and humanity.

"A system which sends 20,000 people to prison every year not for crime but for poverty; which punishes people for physical and mental abnormality and judges sanity by a legal definition nearly a century old; which retains corporal and capital punishment; which seeks to train thousands of antisocial persons in citizenship by subjecting them to a prison regime which deprives them of the only conditions under which they can learn self-control; and which sets them free again by order of a judge who fixes the end of the sentence before the treatment has even begun; such a system is obviously still rooted in mediaevalism."

Moreover, these authors hold that the great reforms of recent years have been made in the right direction. They consider that in penal matters the nation stands at the cross-roads. The increase in crimes against property, largely due to post-war depression, has led to an ignorant demand for a return to old and bad methods. They see a paramount necessity for every citizen to understand the true facts about crime and to resist a stampede into measures which will only aggravate the great evils of the present. This is easily the best book on penal reform that has been published in the last year or two. It has been criticized, probably with justice, by those who actually have to administer the penal system as being destructive and unpractical. Nevertheless, it is necessary to understand an evil before a rational attempt can be made to deal with it, and the book abounds in constructive suggestions which, even if they are not within the realms of immediate possibility, should at least be kept in view as ideals.

Dr. W. A. WHITE is a psychiatrist of very long experience in dealing with insane prisoners in America. He indicates[5] that the problem in the United States has the same elements as in this country, but is much graver. He writes from the point of view of the psychologist—in fact, he describes the book as an essay on the wide topic of human relations, illustrated from the field of criminology. The result is that, although most of his argument is well founded, it is so largely general and theoretical that its appeal as a practical contribution to the problem must be very limited.

OPERATIVE SURGERY

In the third edition of Mr. E. W. HEY GROVES's textbook of *Surgical Operations*[6] some new sections have been included, and a number of illustrations have been redrawn or added. The book is designed for nurses and for medical students, and aims at presenting a simple account of general and special surgical technique. That it has reached a third edition shows that it has proved its use. The general plan remains unaltered, the operations described are those which the student and nurse will see performed frequently in any modern hospital, and the aim of the author has been to make their purpose intelligible as well as to describe their steps in order. There are a few additions which seem worth suggesting. A description of the citrate method of blood transference might be included in the paragraph on blood transfusion in view of its common use and simplicity. The only method described is that by means of the paraffined cylinder. Some further information might advantageously be given about the use of the diathermy knife, and a reference be made to it in connexion with brain surgery; there is no reference to the use of the current for haemostasis. It may not be the author's custom to perform gastro-enterostomy in cases of perforated gastric and duodenal ulcer, but mention might well have been made of it in view of its frequent practice. Special sections are devoted to general technique and sterilization and to the after-treatment of abdominal operations, and at the end of the book there is an appendix of illustrations of instruments.

The amount of surgical knowledge which is expected by the Examining Boards who control the registration of nurses is considerable. The standard which should be

[4] *The Law-breaker.* By E. Roy Calvert and Theodore Calvert. A Critical Study of the Modern Treatment of Crime. London: G. Routledge and Sons, Ltd. 1933. (Pp. xiv + 294. 7s. 6d. net.)

[6] *Surgical Operations.* By E. W. Hey Groves, M.D., B.Sc., M.S., F.R.C.S. A textbook for students and nurses. Third edition. London: H. Milford, Oxford University Press. 1933. (Pp. 263; illustrated. 18s. net.)

expected is a matter on which opinions differ ; as requirements stand to-day the nurse needs a textbook of this kind if she is to acquire a sufficiency of knowledge during her theatre training. Mr. Hey Groves has done the difficult task of simplification well, and the book deserves its popularity.

DRUGS IN INDIA

In compiling so thorough a work of reference as his *Indigenous Drugs of India*[1] Lieut.-Colonel CHOPRA has thought fit to consult numerous works—some of them now difficult to obtain—and to embody the results of the last ten years' research on this subject, as carried out by him in the Calcutta School of Tropical Medicine. The result is of considerable interest. In the first fifty pages of his book he deals with the cultivation of plants in India, its medicinal exports and imports, drug adulteration, and the important problem of what economies might be effected by the use of indigenous drugs of proved value. As the Hindu, Ayurvedic, and Mohammedan systems of medicine appear to have made no progress in the last 1,500 years, the author urges the testing of the more promising of their innumerable preparations by modern scientific methods. It is of interest to note here that such methods have, with few execeptions, proved the drugs so far tried to be valueless. In Part II he deals with the Indian drugs which are of some value, and gives good accounts of our knowledge of such important ones as the aconites, the cinchona derivatives, digitalis, ephedra, cocaine, and opium, etc. Part III comprises a list of drugs which have been used in indigenous medicine—of the value of which little or nothing is known—and includes three pages of the names of drugs recommended for snake bite, many of which have been found by work in the Bombay Research Laboratory to be useless. Six pages are devoted to animal products. We note, however, that rhinoceros urine, the sale of which as a specific for rheumatism furnishes a considerable income to the Calcutta Zoo, has been omitted.

Notes on Books

The Swelling of Proteins and Allied Phenomena[4] is a volume of 124 pages issued by the International Society of Leather Trades' Chemists, which contains the papers read at a conference of the British section of that body last year. The volume comprises ten papers, all of which are of a high standard. Among the contributors are Professor Donnan, Mr. Adair, and Dr. Dorothy Jordan Lloyd. The contributors deal with some of the most difficult problems in colloidal chemistry, and it is interesting to find that definite conceptions regarding the nature of imbibition are gradually being formed. These hypotheses are based on schemes which depict the way in which the polypeptide chains of proteins are packed in gels. The matters discussed are of more immediate concern to the leather industry than to medicine, but they are also important to all who are interested in the problem of the structure of living protoplasm.

The *British Guiana Medical Annual*[5] has reappeared, and its twenty-fifth issue is dated 1932. It is issued by a committee of which the local Branch of the British Medical Association appoints a majority of members. A portrait of Dr. E. D. Rowland, the founder of the *Annual* and a most distinguished member of the British Guiana Medical Service, is reproduced as a frontispiece, with a short biographical note. The contents of the present issue include a record of the *Transactions* of the Branch in chronological order for the years 1925-32, the last three years being dealt with in fuller detail. The bulk of the volume is occupied by clinical articles. In one contribution the development of leprosy work in the colony is traced during the past six years. The range of the topics in this issue indicates the progressive nature of clinical practice and scientific research in British Guiana.

The approach of the holiday season has brought us two books which will be of interest to a good many members of our profession. *The Fisherman's Vade-Mecum*,[10] by G. W. MAUNSELL, is truly an encyclopaedia of fishing for salmon, sea-trout, trout, and pike, compiled from notes and the experience of a practical fisherman and arranged in a very convenient way. It is full of valuable and useful "tips," and should be in every fishing library. *The Angling Resorts of Scotland*,[11] by W. ROBERTSON, is a useful guide to fishing in Scotland. It is conveniently arranged, with a summary of the lochs and streams and particulars of the fishing hotels.

Classified Doses of the British Pharmacopoeia,[12] by B. L. STANTON, is a brochure containing the official doses, a list of the standardized preparations, and the strengths of the galenicals, etc., as given in the new *British Pharmacopoeia*.

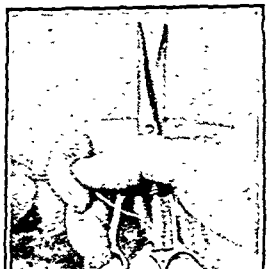
[1] *Indigenous Drugs of India*. By R. N. Chopra, M.A., M.D. Calcutta: The Art Press. 1933. (Pp. 650. Rs.15.)

[4] *The Swelling of Proteins and Allied Phenomena*. International Society of Leather Trades' Chemists. 1933. (5s. 6d.)

[5] *The British Guiana Medical Annual for 1932*. Edited by G. H. Stevan, M.B., Ch.B., and A. G. Coia, M.B., Ch.B. Demerara: *Daily Chronicle* Office. 1933. (Pp. 187.)

[10] *The Fisherman's Vade-Mecum*. By G. W. Maunsell. London: P. Allan and Co., Ltd. 1933. (Pp. 474. 12s. 6d. net.; leather, 17s. 6d.)

[11] *The Angling Resorts of Scotland*. By W. Robertson, M.D. Edinburgh and Glasgow: W. Hodge and Co., Ltd. 1933. (Pp. vi + 139. 2s. 6d. net.)



[12] *Classified Doses of the British Pharmacopoeia*. Compiled by B. L. Stanton, M.R.C.P. Melbourne: W. Ramsay Pty., Ltd. 1932. (Pp. 45. 2s. 6d.)

Preparations and Appliances

"LIGATURE SCISSORS"

Mr. C. ALEX. WELLS, F.R.C.S. (Liverpool), writes: The "ligature scissors" shown in the accompanying figure, which Messrs. Thackray of Leeds have made for me, are peculiar in that the blades are disproportionately long, which results in a bigger movement at the points than occurs at the rings. The shanks are made "bow-legged," and in between them a spool of thread is carried. This turns upon a spindle, which screws into a block fixed to one of the rings, and can be changed with ease.

The scissors are carried on the ring and little fingers of the operator's right hand, in the palm of which they lie, the points emerging between the forefinger and thumb. Some surgeons might consider it worth while having the spools wound with catgut, but personally I use the scissors only with thread, which is previously put through the autoclave. At the time of operation the scissors and thread are boiled up together with the other instruments, and, using a rustless steel pair, I have not found it necessary to resharpen the blade even after two years' constant use in all such perfectly clean and extensive operations as a radical breast, thyroidectomy, or gastrectomy. I cut the knots very short and have had no difficulty from the discharge of fragments, except in one thyroidectomy. The amount of thread contained in one spool is sufficient for any one of these operations.

A considerable economy in catgut is effected, but the real value lies in the time saved when the surgeon ties and cuts his own ligatures, more especially if a regular trained assistant is not always available. Surgeons who are accustomed to carry their own scissors and tie and cut their own knots will find the extra convenience of carrying the ligature material and the scissors together, in this way, well worth while.

STATE MEDICINE AND THE DANGERS OF BUREAUCRACY

A very outspoken address was delivered from the chair of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on June 23rd by Dr. WILLIAM BUTLER, the outgoing president. Dr. Butler retires from the service of the London County Council at the end of July under the rule as to the age limit. Before entering the Council's service in 1912 he was medical officer of health for Willesden. In recording the fact of his retirement, the Central Public Health Committee states that in the performance of his responsible duties Dr. Butler has rendered the London County Council able and devoted service.

THE REIGN OF LIBERTY

In the course of his address Dr. Butler said that the penetration of medicine into the domain of statecraft had resulted in the most profound modifications in the nature and conduct of its practice. Medicine to-day was the collective outcome of personal effort. It was a body of knowledge built up by individual pursuit and instructed practice, the issue of private investigations and findings open and free for all to adopt or reject. The fellowship of medicine had been, perhaps, the freest and most individualistic society that had ever arisen above the horizon of unintegrated anarchism. By no means structureless, it had no heresies or orthodoxies; there was no upsetting view it might not accept under the persuasion of evidence, no tenet it would not forgo under the constraint of fact. Medical practitioners in the widest sense had been the freest and most private of persons, observing, thinking, and doing as they would. The great discoveries of medicine had been conditioned by the assumption of this freedom. Whatever the future might show, medicine as we had it to-day was the embodiment of knowledge and practice that had grown under this reign of liberty. Such liberty as had been enjoyed was very likely only possible because medicine for the most part had been administratively unorganized. Primitive and slightly organized societies permitted a freedom perforce denied to complex communities.

State medicine in respect of liberty was antithetic to private medicine. Medicine in our own time had been private, independent, and aloof from the regulations which civic control imposed, self-determined in a way and degree that no organized State could countenance. And State medicine grew apace. Already it had submerged great tracts of the private field, and threatened to claim the whole domain. Of less than a century's growth, it had in the last two decades advanced its dominion far across the private frontier. Under these conditions would medicine sustain its triumphs? Was there ground for misgiving that under the new regime the fruits of endeavour would wilt, the endeavour itself be stifled, originality of thought, initiative, and the opportunity for their exercise be overgrown by mechanized systems wherein man was replaced by an impersonal team and a soulless administration?

THE OLD ORDER AND THE NEW

In its earlier phase State medicine claimed only the part-time service of a practitioner. Whole-time appointments when they arose were confined at first to Government departments, and presently were extended to the larger local authorities. Whole-time medical officers multiplied, justified their existence, and extended their field of operations. Instinctively antagonisms developed between the old order and the new. The solidity of medicine was threatened, and the disruption into official and private branches had culminated at times in mutual distrust and recrimination. There had developed—by no means universally, but enough to be mischievous—a lack of tolerance by the newer for the older forms of practice. The private practitioner had felt this growth of hostility, this lack of sympathy with him in his difficulties, which were so very much greater in his wide field and with his limited resources than those of his official brethren, with their narrower outlook and State-supported reserves; and he had not been helped by the exclusive turn which in relation to him had been given to the development of the State medical service. To take only one example, the tuberculosis officer was efficient in his restricted domain, but disease presented to him only one face, not the multiplicity of problems inevitably forced upon the practising physician, and he was apt, therefore, to direct the organization of medical services at the dictation rather of facility of administration than of an embracing outlook bringing in the essential unity of medical work. Dr. Butler made it plain that he was only taking the tuberculosis officer as an illustration of what was equally true in other departments.

Greatly as national health insurance practice had been criticized, and grave as might have been many of the defects in so wide an absorption into a State service of the poorest-paid work in medicine, the line of advance by inclusion of the established practitioners, rather than by the creation of new and independent officers to the exclusion of the existing profession, was in contrast to the development of the preventive side of State medicine; these distinctive lines of development focused at this point, and State medicine would take its character from the line which at this point of bifurcation it followed. School medical inspectors, tuberculosis officers, medical officers engaged in maternity and child welfare could all be recruited by the part-time employment of medical practitioners otherwise engaged in the general and specialized practice of medicine and surgery. The benefits to the official and to the practising branch of the profession by this arrangement would be mutual, and though administration would be more difficult, that would be a small price to pay for attaining the solidity and freedom of medicine. Uniformity on these lines might not be practicable, but in large urban areas a reversal of current practice was called for if the State medical service was to be saved from degenerating into a bureaucratic system.

The recent transfer of Poor Law hospitals to the county and county borough councils marked a greater advance in the development of a State medical service than the mere transfer of institutions from one body to another would indicate, for it was an assumption by the authorities of responsibility for hospital provision to meet the needs of the community so far as they were not already met. What this might portend they were all too near to the event to judge, but State medicine in its institutional development had taken its place beside State education, and it was scarcely avoidable that in time it should become all-embracing. It was the more necessary that at this stage the bias of all that medicine needed for its fostering should be given in the trend of its prospective growth.

CONFLICTING TRENDS

Was that trend to be bureaucratic, or was there to be continued the freedom of medicine? That was the issue, and it was momentous. Centralization, subordination, control, a militarized machine, with its precision of action and red tape, was the alternative to the retention by medicine of its freedom to be developed on its own lines and by its time-honoured methods. In private medicine the practitioner found what he would, and proclaimed what he had found, though it were shattering to the politician, an affront to the ecclesiastic, or anathema to the head of a department. There was no room for such excursions in a bureaucracy. The official was no longer a doctor moved from within by the light of his profession. He was free to think what he liked, but not to say or to do. The opinions he formed on matters he was charged to deal with might be presented or suppressed, adopted without acknowledgement, or changed and mutilated without his concurrence or even his knowledge. No longer at liberty to follow his bent, to select and retain the particular field in which he loved to work, he would be directed by a will other than his own. His relation to the head of his department was not that of practitioner to

consultant. It was not necessarily that the chief officer usurped the claim of the worker to the fruits of his labour, or stole the kudos normally awarded to original accomplishment. The chief officer, like his subordinates, was the victim of a system imposed by the tradition of bureaucratic government. But medicine could be fitted into it only with loss. For its suitable organization medicine called for a different type of administrative machinery. Its association with the State might be as intimate as public requirements demanded, but its relations must be looser and freer from departmental regimentation. The most human of men, the practitioner, must be left with scope for the play of his human virtues and weaknesses. The perfection of a surgical technique within the limits of municipal appointment by monotonously repeating a single operation would be an achievement scarcely worth the sacrifice of surgical enterprise that had given surgery its astounding victories.

But there was a worse fate, Dr. Butler continued, than the bureaucratizing of the practitioners of medicine—namely, to be regimented under the heel of lay bureaucrats. Whatever the evils medicine might suffer in becoming officialized under a homogencous and uniform organization, these were nothing compared with its fate should practitioners be mobilized and subordinated under the unsympathetic aegis of lay administrators. This was still to be apprehended as a possible ultimate danger. Doctors were instinctively disliked and distrusted by local authorities, whose outlook was primarily political. The uncompromising logic of facts presented with an impartial eye and leading to the unpleasant conclusions in which truth was prone to issue was incomprehensible and repugnant to such bodies. So far the instinctive struggle incessantly waged by medical officers had warded off the aggressive encroachments of the lay officials, but the struggle went on. The medical officer had a field wide enough for all his activities and coveted no man's vineyard. He was defensive only in his own domain, and sought to invade no foreign territory. If a battle was lost, he was shorn of his own ; if gained, he only retained it. All this was part of the bureaucratic process. This vicious trend might, of course, represent only the childish ailments which followed entry upon school life. But in the world organization of social activities everywhere to be observed isolated segregation was no longer possible. In the structuring of the new world now taking place it was necessary to see that it was so shaped that it left scope for the retention of individuality. It was so easy for those in administrative work to forget that they were administrators of medicine, and served primarily in its ranks. Dr. Butler ended by saying that he had spoken "as a bureaucrat to bureaucrats."

DISCUSSION

Professor MAJOR GREENWOOD, in proposing a vote of thanks, said that those present could hardly help sharing Dr. Butler's pessimism, though he himself thought there was a tinge of optimism in the prospect. Whenever he attended a comitia of the Royal College of Physicians he realized humbly that he as one of the "bureaucrats" could hardly rise to that serene atmosphere which pervaded such a body. And yet he took heart when he noticed that, although not actually the youngest person present, he would be regarded, even though in the early fifties, as one of the juniors. When all was said about "encroachments" of bureaucracy, it would still be true that probably the majority—certainly, if not the majority, a very large minority—were what the true-blooded Socialist rudely called "private adventurers." He found a parallel to the present transition in the state of the world at the time of the break-up of paganism. At that time really educated people of the ancient school—people like the Emperor Julian, for example—must have regarded the early Christian Church with a feeling akin to physical nausea, fearing that, with its disregard of all art and literature that really mattered, it might come to dominate the world. Yet, in the Middle Ages, there was reached the freest intellectual society that had ever existed in the world, the truth being that in a State where everybody was more or less an official of the Church one got a comprehension of all intellectual society, and attained really free thought. Was it not probable that a time would come, with the advent of the new generation, when everybody was more or less in the fold of bureaucracy, and within the bureaucracy itself there would arise the same intellectual differentiation as was found among the scholastic philosophers of the Middle Ages?

Sir WILLIAM HAMER, in seconding, contrasted the address with the presidential address to the Metropolitan Counties Branch of the British Medical Association to which he had listened earlier on the same day (*Supplement*, July 1st, p. 12). To a public officer Dr. Scott's address was the Turkey rhubarb, and Dr. Butler's the comforting jam!

A REPORT ON THE CLINICAL VALUE OF "EVIPAN"

(FROM THE ANAESTHETICS COMMITTEE, MEDICAL RESEARCH COUNCIL)

Encouraging accounts of the action of yet another barbiturate anaesthetic, "evipan," which came from German surgeons and anaesthetists, seemed to the Anaesthetics Committee to warrant a thorough clinical trial. Twenty-five thousand cases are reported from that country with one death attributed to "evipan." Accordingly, the offer of Bayer Products, Ltd., was gladly accepted, and supplies of the new drug were put at the disposal of the committee. In making use of these the committee had the co-operation of a number of anaesthetists, who have sent details of their cases and the opinions which they have formed. At St. Bartholomew's, Messrs. F. T. Evans and Rait-Smith ; at Guy's, Mr. R. C. Brock ; and at St. George's, Messrs. Douglas Belfrage and E. Landau have assisted in this way; and Dr. J. M. Barlet, Mr. C. Borland, and Mr. R. Jarman are others who, with Mr. C. Pannett, Sir Francis Shipway, Dr. C. F. Hadfield, and Dr. J. Blomfield, members of the committee, have furnished the material for this report. Evipan sodium is the sodium salt of *n*-methyl-C-C-cyclo-hexanyl-methyl barbituric acid, and dissolves freely in water, but the solution is stable only for an hour or two. Thorough pharmacological work carried out in Germany showed the drug to have a high therapeutic quotient in cats and dogs. In the former 25 mg. gave full anaesthesia, while the lethal dose was from 100 to 110 mg., a quotient of 4, and in dogs the quotient was 3.3. Parsons found that in the cat 0.1 c.cm. of a 10 per cent. solution caused a fall in blood pressure of 25 mm. Hg, with slow recovery, and apnoea for twenty seconds. After a total of 0.6 c.cm. of 10 per cent. solution artificial respiration was needed and the blood pressure fell until death. The anaesthetic action of the drug was rapid in onset and short in duration. It is not a volatile anaesthetic, but it is very rapidly detoxicated by the liver. Rabbits decompose half the narcotic dose within thirteen minutes. Traces of the unchanged substance are excreted in the urine. By-effects in animals were found to be slight. The blood pressure fell 15 to 20 mm. Hg. The pulse remained regular and full. Overdose caused cessation of the breathing, the heart continuing its beat for a considerable time after. Blood sugar was unaltered and other evidence of effect on body metabolism was of the slightest.

TECHNIQUE AND DOSAGE

When used for anaesthesia evipan is given intravenously. At first the drug was issued in ampoules each of which contained 3.5 c.cm. of 33⅓ per cent. stable solution in methyl-diglycol. Three c.cm. of this contained 1 gram of evipan sodium. Ampoules containing 7.5 c.cm. were also issued, and before use 3 c.cm. of the concentrated solution were drawn into the syringe and expelled into the ampoule containing the distilled water. The evipan solution was sticky, and required, therefore, a larger needle than the ordinary hypodermic size. Now, however, the evipan is supplied in powder form in

ampoules to which the distilled water supplied in another ampoule is added. By aspirating and reinjecting once or twice a solution is obtained which passes easily through the ordinary hypodermic needle. This is inserted into a suitable vein of the arm with due antiseptic precautions. It is advisable to have the arm held steadily by a second person because of the twitching of muscle which often comes on early after injection has begun. The solution is run in at the rate of 1 c.cm. in fifteen seconds. Dosage is determined by the characteristics of the patient and the results noticed. Acting on a definite scale arranged according to body weight does not give satisfactory results. An average amount to produce unconsciousness is about 3 c.cm. A good plan, recommended by Lauber of Königsberg, who has had a big experience, is to make the patient count. When the counting ceases through sleep the amount that has been injected is noted, and the same amount is further added for a short operation, and twice as much for a long one. In elderly and feeble people, and those who have gone to sleep exceptionally quickly, only half the amount which produced sleep is added. Most patients are asleep in about one minute. There is often some twitching or jactitation, but often complete relaxation of the muscles of tongue and jaw occurs early, and care is needed to preserve a patent airway. Generally speaking, 10 c.cm. are regarded as the maximum dose. When it is desired to complete a longish operation under evipan only, the needle must be left *in situ* and a further injection made when the anaesthetic effect of the first is obviously wearing off. Used in this way as much as 20 c.cm. has been injected. There is, however, a fluctuation in the anaesthesia, and we do not see evidence of any advantage in the use of evipan for other than short operations—that is, of twenty minutes or so at the outside.

SYMPTOMS PRODUCED

A deep yawn just before the disappearance of consciousness is a common symptom. The great majority of patients fall asleep perfectly quietly. Twitching of face muscles is common, and there is sometimes jactitation of limbs. In one instance tonic contraction of many muscles and brief stoppage of respiratory movements were observed. The degree of muscular relaxation varies, but is rarely extreme or sufficient for an abdominal operation. The pupil is usually moderately dilated but active to light. In the early stages it is sometimes widely dilated. The conjunctival and, generally, the cornea reflexes have disappeared at the moment of fullest effect. Even then reflex movement at the start of operation has been seen many times. The eyelids are sometimes widely separated. The effects on blood pressure are slight. There is commonly a fall of about 20 to 30 mm. Hg, which is quickly recovered from. Respiration is often somewhat slowed, but there has been seen no serious depression except in one instance when, unknown to the anaesthetist, the patient, an elderly woman, had received a full dose of morphine and hyoscine before the evipan. The combined result was respiratory stoppage requiring, and removed by, artificial respiration and CO_2 with oxygen. It is inadvisable to give any sedative before evipan. No special preparation is needed, but it is of course desirable to have the stomach empty. Subjective symptoms as described by reliable patients are a feeling of quickly increasing lassitude which cannot be overcome and loss of consciousness in a few seconds. Experience shows, nevertheless, that it is best to wait two minutes after completing the injection before beginning to operate. The length of time of unconsciousness is usually about ten to twenty minutes after an average dose. After this time the patient can talk but is sleepy, and will drop off again if left quiet. When he finally wakes he remembers nothing after the first prick of the needle. As in the case of other anaesthetics there is considerable difference in the reaction of different persons to evipan, and the exact behaviour cannot be foretold. The patient may go to sleep with no apparent difficulty and the usual signs of anaesthesia be present, and yet there may be movement on incision to an extent demanding a supplementary anaesthetic. On the other hand, it often happens that merely 3 c.cm. give a perfectly satisfactory, though of course only a short, anaesthesia. Our experience does not corroborate the statement of Ernst that one can reckon almost always on half an hour's good anaesthesia. We are led to believe that in Germany the surgeon is satisfied with a narcosis which is not regarded as enough by most operators in this country. Certainly the German reports describe a more constant and sufficient anaesthesia than has been obtained here by the same dosage and technique.

CONCLUSIONS

It is obvious from what has been stated that evipan is not to be regarded as a basal narcotic in the sense that, for example, nembutal and avertin are. Its action is so evanescent that it cannot be employed, as are these drugs, for procuring a longish period of quiet or of unconsciousness before the administration of the anaesthetic proper, nor can it be used, as are the basal narcotics, to put the patient to sleep in his bed in order to avoid all knowledge of transference to the operating theatre. If it is used before another anaesthetic this must follow closely on the administration of the evipan, and as a preliminary, therefore, it is to be classed with nitrous oxide and ethyl chloride rather than with the basal narcotics. For those who like intravenous methods it is certainly an admirable means of inducing anaesthesia, all opinion agreeing as to the rapidity and pleasantness with which the patient becomes unconscious. Excitement or restlessness during induction have been seen only in unusually emotional subjects. After-effects also are of rare occurrence. It can be relied on for an excellent anaesthesia in minor surgery—that is, for short operations when the possibility of slight reflex movement is not a matter of great concern. It is true that often the anaesthesia is profound, and that by repeating the injection it can be prolonged; but it is not obvious that this is a better procedure than usual methods, such as gas and oxygen, for example. The recovery free from after-effects and the quiet induction make evipan a valuable agent in the case of persons gravely ill for whom a short anaesthesia is desired for any reason. There are many such instances when it would probably be preferable even to nitrous oxide. Two examples of this kind may be quoted from our series.

A man, aged 62, suffering from aortic regurgitation and arteriosclerosis, had amputation of the great toe for gangrene. He received 6 c.cm. evipan. Sleep was induced in half a minute. The operation took ten minutes, during which time the anaesthesia was all that could be required. After twenty minutes he woke up yawning and was talking a minute later. Half an hour later he fell asleep and slept for six hours.

The other example was a man of 36 years, extremely ill with empyema after pneumonia. He was regarded as unfit for a general anaesthetic. Nevertheless, it was decided to use evipan, of which 10 c.cm. were injected. Anaesthesia was good, and the operation, rib-resection, was completed without anxiety. The patient was fully awake after three-quarters of an hour, and suffered no after-effects.

A few trials have been made of the efficacy of evipan by the mouth. It is described as proving less efficient thus given than nembutal in the same circumstances. Nevertheless, two or three of the tablets in which it is provided for oral administration are a useful hypnotic, generally causing sleep in a short space of time. It is a useful agent with which to break a habit of sleeplessness.

At the annual general business meeting of Dr. Barnardo's Homes: National Incorporated Association, the report showed that 113,236 destitute boys and girls had entered the homes up to the end of 1932, and that 1,735 boys and girls and babies were admitted during that year—1,531 permanently and 204 temporarily. About 80 per cent. of the admissions came from the provinces and 20 per cent. from the metropolis. Almost every county was represented in this total of admissions. At the end of the year 8,420 children were in residence; 410 of the children are of the sick, crippled, or afflicted class, yet the death rate among the Barnardo family is remarkably low, only 3.37 per 1,000 in 1932, and this notwithstanding that the majority of the children when admitted had suffered from privation, malnutrition, or in some other way. There are several hospitals, hospital homes, and convalescent homes attached to the work, and during the year a new convalescent home was opened at Bognor Regis.

British Medical Journal

SATURDAY, JULY 8th, 1933

THE UNIVERSITY OF LONDON

On June 26th, in the presence of a company representative of all branches of learning and of many nations, His Majesty the King laid the foundation stone of London University's new buildings. "She has waited long," said His Majesty, "for a home that she could truly call her own, and we all now rejoice to see the beginning of a finely planned group of buildings which will serve as headquarters for her far-reaching work and influence." This influence has indeed been far-reaching. To thousands it has been of that noblest kind expressed in Mr. Drinkwater's Graduation Song:

> In field or market-place or mill,
> Beneath a dear or alien Sun,
> We'll build a generation still,
> Of faith and honour here begun.

Even to those to whom the University of London has been no more than a relentless setter of questions, she has at least brought home realization of the difference between knowledge and half-knowledge. Perhaps, if we could know the lives of all the thousands who have graduated in this university in the 100 years of its existence it would not be the famous scholars and scientific investigators on her roll whom we should proclaim to have been her greatest glory, but men and women who lived and died unknown to fame, yet had been encouraged by the mere "examining body" to discover for themselves something of the beauty and the marvel of science and the humaner letters.

But most of us are helped by the external symbols of spiritual things and have lamented that the metropolitan university lacked any such embodiment. A Londoner visiting Oxford or Cambridge can admire without envy, for he may reflect that in these pleasant places towns have grown up around colleges, but London could never be a pendant to any university, however august. The Londoner's admiration of the University of Glasgow's buildings might be tinged with envy, for the site has been so chosen that, although teachers and students are undisturbed, the youngest of them, looking down on the great city, could not make the mistake of thinking that the town exists for the university. The new buildings of London University will not command so fine a prospect as does the University of Glasgow, but they will enjoy a reasonable peace, and those who work in them will be in no danger of forgetting that university life is but a fraction of human experience. Those who work there will, indeed, be a very small proportion of London's university population; to most the building must be not a workplace but a symbol. London's undergraduate teaching cannot, of course, be concentrated in any one building; in the future, as in the past, the most precious memories of student life will be of that best of education gained "in the argumentative walk or disputatious lounge: in the impact of young thought upon young thought, of fresh thought on fresh thought, of hot thought on hot thought: in mirth and refutation, in ridicule and laughter"; *those* memories will, for London graduates of our profession, hallow "Bart's," "Guy's," "The London," and other schools already old when the University was in swaddling-clothes. But, just as in an alumnus of Oxford or Cambridge, love of his college feeds loyalty to his university as representing something greater still, so to a London graduate the palace which is to be built in Bloomsbury should be a symbol and an inspiration of a greater loyalty. London University is the greatest federal university in the world; no other has to shoulder such varied responsibilities. In the past, men of good will, each emphasizing unduly this or that side of the University's work, have had differences of opinion which at times became so acute as to endanger the common cause. The new building is to be a symbol that those times of dissension are over; the pledge of a new age, or, perhaps, of the return of the golden age which Mr. Drinkwater's song exhorted London maids and London men to bring in again:

Magnus ab integro saeclorum nascitur ordo.

The part of the medical faculty in the development of London University has been large. There are at present more than 500 appointed and recognized teachers of the University in the faculty of medicine; no other faculty includes as many as 400. This generation has witnessed an immense development of medical teaching in London; the teachers will not suffer by comparison with their predecessors, and they enjoy material facilities undreamed of thirty years ago. Yet the position is not wholly satisfactory. It is still true that a large proportion of those who receive the whole of their institutional and professional training in the London schools never graduate in the University of London. It is even true that a sensible proportion of the students of that University who pass the second examination for medical degrees never graduate. We believe that this can be said of no other British university, and a difficult problem awaits solution—namely, how to increase the proportion of medical graduates without lowering the standard of the degree. It is common knowledge that the present medical curriculum, not in London only but throughout the British Empire, is proving a serious strain on both teachers and taught, and that the whole subject is under the consideration of a conference appointed at the close of last year on the initiative of the University of London. The membership of this conference, which includes representatives of the Universities of Oxford, Cambridge, and London, and of the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries, was given in our issue of December 10th, 1932. A special committee on medical education has also been set up by the Council of the British Medical

Association, and its interim report appeared in the *Supplement* of June 24th, 1933 (p. 283).

The problem under the consideration of these committees is a difficult one—namely, how to frame a curriculum which, while providing adequately for technical instruction, shall be fundamentally educational, in the highest sense of the word education, and capable of completion within a reasonable number of years. But, as anybody familiar with the history of the University of London will remember, only a few years ago the stage reached on June 26th seemed impossible of attainment. We may therefore reasonably expect, as well as hope, that the university problem which is of such interest to our profession will also be solved, so that London medical students of the future *may partake more fully than now of the advantages* of a university education.

HAFFKINE'S PLAGUE VACCINE

In September, 1896, plague broke out in Bombay, the starting-point in its invasion of India. At this time Haffkine was in India engaged in field trials of his vaccine for cholera. His services were secured by the Government of Bombay, and in October he commenced his studies on the bacteriology of plague. Within three months he evolved his method of preparing a vaccine, proved that it protected animals against inoculations of virulent cultures of *Bacillus pestis*, and demonstrated the harmlessness of his prophylactic to man by experiments on himself. The value of the vaccine as a means of individual protection was effectively demonstrated before long. About half of the inmates of a certain jail were inoculated, the remainder being kept as controls. Plague invaded the jail, and of 148 inoculated prisoners only two contracted the disease, both of whom recovered; while in 172 uninoculated there were twelve cases with six deaths. The publication of these figures caused so widespread a demand for inoculation that manufacture on a large scale was begun, with the result that to-day Haffkine's vaccine holds a primary place among plague preventive measures in India, where, in all, some thirty-six million doses have been issued for use. In his memoir on the subject, Lieut.-Colonel J. Taylor[1] points out that many years of observation and experiment have confirmed the value of the methods originally adopted by Haffkine, and, although changes and improvements have been made in details, the principles laid down by him have not been departed from in any essential. The author analyses records relative to more than 300,000 persons exposed to plague risk, of whom over 40 per cent. were inoculated, and concludes that Haffkine's vaccine gives approximately a fourfold protection against attacks of plague and an eightfold protection against death.

Less striking results than these were obtained during the Java epidemic of 1920–3. Here the procedure was to inoculate half the members of each family under observation in such a way as to provide for each protected person an uninoculated control, so far as possible of the same age and sex. Some such alternate system, Dr. de Vogel[2] asserts, must be adopted in order to obtain figures which are strictly comparable. The Java records deal with nearly 80,000 persons, of whom approximately one-half were inoculated with Haffkine's vaccine. Owing to the impossibility of securing proper medical surveillance of all cases of febrile disease and the consequent uncertainty in diagnosis, these statistics include only cases of plague which ended fatally, the diagnosis being determined by spleen punctures made after death. The mortality in the inoculated was one-half of that in the unprotected, a result considered disappointing. The epidemic in Java was due to a concurrent epizootic in rats, and there was no evidence of any cycle of infection from man to flea and flea to man. Consequently, it is contended, mass inoculation failed to control the disease, for the source of infection was unaffected, and the epidemic resumed its march when the protection conferred by the vaccine diminished or disappeared. Moreover, mass inoculation is less practicable in Java than in some other countries, for, owing to the climate, plague continues unabated throughout the year, and so there is no quiescent period when organized inoculation on a large scale might profitably be undertaken. For these reasons it was considered inadvisable to harass the population any longer by inoculation propaganda. Instead, all energies were concentrated on measures calculated to expel rats from houses and huts (for the local rat responsible for human plague is dependent on man for shelter), with results which are stated to have been highly successful.

The importance of the man-flea-man route of infection is emphasized by Dr. Ricardo Jorge[3] in the course of a fascinating dissertation on the history and epidemiology of plague. Dr. Jorge argues that in epidemics such as the Black Death this method of spread played an important and often even an exclusive part. Everyone in old times, he points out, whatever his social rank, was surrounded and infested by *Pulex irritans*, and so infection would easily be transmitted from person to person. Doubtless this statement is true as regards insect prevalence, but it might equally be employed to support the contention that in such conditions rat plague would be transferred to man all the more readily. *P. irritans* is most catholic in its tastes, and animals in flea-infested dwellings can be found literally swarming with human fleas which parasitize their alien hosts with the utmost content. The man-flea-man route probably serves to spread the disease in certain circumstances, but whether an epidemic of bubonic plague could maintain itself in man without an existing reservoir of infection in animals is open to question. Whatever our views on this particular point may be, Dr. Jorge's scholarly paper is well worthy of study.

CANCER OF THE SKIN

A great deal has been learnt about the aetiology of cancer by a study of cancer of the skin. Here the disease can be recognized at a comparatively early stage, and a direct relationship can be traced to influences which appear to have predisposed to malignancy. One of the most important of these predisposing influences is occupation, shown particularly in workers exposed to soot, tar, radiations, and mineral oil. In the forms of skin cancer associated with these occupations it has been comparatively easy to prove the dangerous character of the patient's work, but in other types of skin cancer no obvious relationship to occupation has been discernible by ordinary clinical methods of inquiry. It is interesting to learn from Dr. Gretta Thomas's report on cancer of the skin, recently issued by the Ministry of Health,[1] that a careful study of occupation in relation to skin cancer has not revealed any new environmental conditions which predispose to malignant disease. In the majority of cases of cancer of the skin there is no evidence of the operation of a carcinogenic agent in the industrial environment. Next to the influence of occupation on the development of cancer might be placed the knowledge we have gained from skin cancer about the general structure of tumours in their early stages and the relation of benign to malignant tumours. With cancers of internal organs we have no means of finding out what was the size or shape of a tumour a few weeks or months before its removal. It is extirpated at a certain stage of its development: its early characters can only be inferred from the clinical history. Such observations as are possible all go to show that very many malignant growths develop in pre-existing non-malignant tumours or in injured or diseased tissues. With cancer of the skin the evolution of the disease can be watched and measured. One of the subjects to which special attention was directed in the recent Ministry of Health study of skin cancer was the relation of malignant diseases to preceding lesions, and the evidence collected provides very many examples of the development of cancer in previously existing non-malignant lesions of the skin. We have mentioned two aspects of the cancer problem which have been clarified by the study of skin cancer, but there are other features of the growth of epithelial skin tumours which appear contrary to expectations. For instance, in cancer of the lip there is a very peculiar difference in sex distribution. Cancer of the lip is about twelve times as common in men as in women, and the percentage of deaths from lip cancer to the total for cancer in England and Wales is 1.1 for males and only 0.1 for females. Now cancer of the lip is twenty times as common in the lower lip as in the upper, but when the upper lip is affected it is surprising to find that the susceptibility is reversed. What factor is there which can be responsible for this unequal distribution of cancer of the lip in the two sexes? It has been suggested that the minor injuries inflicted during shaving or irritation from sessile clay pipes may be contributory factors, but such explanations seem very inadequate. This sex distribution of lip cancer is unexpected and odd, but not the only instance of the unexpected in tumour pathology. Others may be found in the detailed survey of cancer of different regions of the body which forms the main content of the Ministry of Health report. The figures and opinions are based on an analysis of 503 cases of epithelioma of the skin treated in the General Infirmary at Leeds during the period 1911 to March, 1931, inclusive. The method of investigation adopted was as follows. The names of all patients with skin cancer appearing in the histological reports were first collected and then looked up in the clinical records. Most of the patients living within about a twenty-mile radius of Leeds were personally inquired for and interviewed, or in the case of those who had died, relatives and neighbours were questioned. Other patients living further away were traced by letters to them or their doctors. The carefully tabulated information provided by Dr. Gretta Thomas is a valuable contribution to the literature of skin cancer, and will be found useful for reference purposes.

THE DIABETIC MOTOR DRIVER

A. Norgaard[1] makes a useful contribution to knowledge in discussing the conditions under which a diabetic should be granted or refused a driving licence. In some countries the problem is of considerable numerical importance. In Denmark, for example, the number of diabetics has increased enormously since 1890: in the five-year period 1890–4, only 86 patients were admitted to hospitals in Copenhagen for this disease, while the corresponding figure for the five-year period 1910–14 was 710, and for the five-year period 1925–29 it was 2,728. At present that country probably has about 5,000 genuine diabetics between the ages of 15 and 65, and among them there must be at least 3,000 receiving insulin. Of two conditions to which the diabetic is liable—coma and insulinism—the first is not likely to cause motor accidents because it develops so gradually. Insulinism, on the other hand, may supervene with catastrophic speed. Apart from its more pronounced signs such as giddiness, tremor, diplopia, weakness, and convulsions, there is another symptom-complex to which Professor Sonne has recently drawn attention. The patient becomes dazed, does the most extraordinary things, wanders aimlessly about without knowing where he is, and lacks initiative, although his outward appearance may present nothing remarkable. Sonne observed transient psychic abnormalities in 54 per cent. of his insulin-treated out-patients, and Norgaard has observed insulinism in 220 out of 777 diabetics. It is also significant that insulinism occurs more frequently outside than inside a hospital, being often provoked by the exertions and irregularities of daily life. Some diabetics are more subject to the condition than others, and while some are warned by prodromal symptoms, others are not. Hence Norgaard's conclusion that insulin treatment would be an indication for withholding a driving certificate. Diabetics not receiving insulin are at this stage of the disease comparatively safe as motor drivers. But the overwhelming majority of young diabetics must sooner or later take insulin, and it may well be a mistaken kindness to grant a driving licence to a young diabetic who wishes to earn his living as a motor driver; for, later in life, when it may be difficult for him to change his occupation, the advent of the insulin stage of his diabetic career may, by disqualifying him for motor driving, penalize him seriously.

SIGHT-SAVING CLASSES AND THE CLASSIFICATION OF BLINDNESS

The International Association for the Prevention of Blindness has issued two reports that are of moment.[1] The report of the annual meeting, held in Paris in November last, is a document of fifty pages devoted wholly to the consideration of sight-saving classes or myope classes. There are printed papers read by Professor Pierre Villey of the Valentine Haüy Association; Mr. N. Bishop Harman of London (whose paper was published in the *Journal* on January 28th last); Mrs. Winifred Hathaway of the National Society for the Prevention of Blindness of the United States; Professor Martin Bartels of Westphalia; Dr. Auguste Dufour of the Central Swiss Union for the Blind; MM. Redslob of Strasbourg and A. Monbrun of Paris. Each of the papers dealt with the experiences of the authors in the working of these classes in their own countries. They therefore form a representative and highly informative body of evidence as to the scope and value of these classes. It was announced that at long last the French Minister of Education had authorized the opening of a class in Paris. All these papers have been translated into English. At the general assembly of the Association held in Madrid in April last the main subject of consideration was the classification of causes of blindness. Papers were read by Professor Marquez of Madrid, Mr. Bishop Harman, and Dr. Marx of Rotterdam. There was a discussion, in which Dr. A. J. Ballantyne of Glasgow took part. The report of this meeting has been published, the papers being in French. It shows that there are two schools of thought displayed in this matter. One, as exemplified by Scottish and North English schemes, advocates a highly elaborate schedule which seeks to cover an enormous mass of detailed information; and the other, advocated by Mr. Bishop Harman, and adapted for use by the London County Council and some other councils, which seeks to bring the different causes of blindness into a minimum number of categories. The assembly appointed a commission to examine and report on the problem of the classification of the causes of blindness, with Dr. Maziny (Egypt), Professor Marquez (Spain), Dr. Park Lewis (U.S.A.), Professor de Lapersonne (France), Mr. Bishop Harman (Great Britain), Dr. Marx (Holland), and Professor Van Duyse (Belgium) as its members.

IMMUNIZATION AGAINST TETANUS

In a recent communication, E. Sacquépée[2] draws attention to the occasional failures that are encountered in the attempt to prevent tetanus by the injection of antiserum. It is known that the effect of the serum wears off in about a fortnight, and that if tetanus bacilli are still present in the wound they may give rise to disease. In such cases tetanus develops after a long incubation period, often several weeks or months. In order to prevent the development of this late tetanus Vallée and Bazy, during the late war, recommended and successfully practised the active immunization of wounded persons by the injection of iodized toxin, over and above the usual passive immunization by the injection of serum. Since that date it has been found that the treatment of toxin with formol gives rise to a non-toxic substance which still retains its antigenic activity. This so-called anatoxin has been shown to be of value in the immunization of horses and of laboratory animals. In 1931 the use of this anatoxin was officially recommended for the prophylactic treatment of wounded soldiers in the French Army. The directions were that every wounded man in whom the development of tetanus was to be feared should be inoculated subcutaneously with 1.5 c.cm. of anatoxin, followed some minutes later, and at a different site, by a suitable dose of serum. A second dose of anatoxin should be given twenty days, and a third thirty days later, 2 c.cm. being injected. To judge the efficacy of this treatment the author has tested the antitoxin titre of the blood serum of 240 patients six months after the injury. Taking one unit of antitoxin as that amount capable of neutralizing a quantity of toxin corresponding to 1,000 lethal doses for a 350-gram guinea-pig, it was found that the distribution was as follows: 1 serum contained 1 unit; 6 serums contained 2/3 U.; 120 serums 1/5 U.; 68 serums 1/15 U.; 10 serums 1/20 U.; 22 serums 1/25 U.; 4 serums 1/30 U.; 3 serums 1/40 U.; 3 serums 1/50 U.; and 6 serums less than 1/50 U. per c.cm. It is not known how much antitoxin must be present in human serum to prevent the development of tetanus, but there are grounds for believing that the quantities found in these serums do represent the existence of a definite degree of immunity. The author concludes that anatoxin vaccination can be efficaciously combined with preventive serum treatment.

HOSPITAL POLICY AT BARROW

In this week's *Supplement* (p. 20) will be found an account of the dispute between the staff and the council of the North Lonsdale Hospital, Barrow-in-Furness, which has led to the threatened resignation of the former. The staff, in accordance with the Hospital Policy of the British Medical Association, wishes to secure for reward of professional services a percentage of the money paid to the hospital under a contributory scheme: the council of the hospital is unwilling to grant its request. Since its inception in 1908 the Hospital Policy has undergone considerable modification in the light of increasing knowledge and experience, but its fundamental principles have found ample vindication in the rapid change in hospital development during the last few years. It is upon a recognition of this change that the Policy is based. In the words with which it opens:

"Among the social changes of recent years none is more remarkable than that which has taken place in our hospitals. Originally charitable institutions for the general treatment of the very poor, they have become centres of highly specialized and complex service to which four-fifths of the population look for help and where the community as a whole claims as a right services which can only be rendered by a great organization or its dependent branches. Voluntary hospitals have become increasingly the hospitals of the worker and his dependants."

While the hospitals confined their attention to one class of the community, the poor, the profession gladly gave its services without thought of payment or reward. But to-day it supplies a wider, more specialized, and

[1] Association Internationale de Prophylaxie de la Cecité, 6C, Boulevard S. Michel, Paris, VIe.
[2] *Paris Méd.*, June 3rd, 1933, p. 491.

more technical service to the vast majority of the community, including those who can contribute directly or by insurance to its cost. The medical profession can no longer offer gratuitous service to men and women who neither need nor wish for charity. The contributory schemes, which are growing with extraordinary rapidity, are organizations not of the poor but of the provident. To become a contributor is to make a wise provision on an insurance basis for the possible contingency of illness requiring hospital treatment. The medical men and women upon whose skill and knowledge the hospital provision depends are—as a direct payment for their services—entitled to a proportion of the payments made by a contributory scheme in respect of its members. In Barrow-in-Furness the council of the North Lonsdale Hospital is unwilling to make this provision for its medical staff. In this industrial area approximately 80 per cent. of the population fails within the ordinary hospital limits of income. The workman who pays 2d. a week is entitled to full hospital facilities. No income limit is imposed. As is clearly set out in the detailed statement of the present position in our *Supplement*, the local profession has been forced by the hard circumstance of dwindling private practice to recognize that it is giving in hospital, without recognition or reward, a service that it formerly gave in private practice in return for reasonable fees. The Association suggests that of the total sum paid 20 per cent. should pass to the staff fund for payment of the doctors who do the work, but the Barrow-in-Furness Division, not unmindful of local and national depression, has shown its willingness to accept a proportion as low as 1 per cent., provided the fundamental principle is conceded. This dispute is of more than local importance, and members of the Association may well await the outcome of the present conflict with interest and concern, for nothing is more certain than that ultimately the interests of many who are now but observers will be profoundly affected. The Council of the Association has been acquainted with the details of the position, and has intimated its full support of the Barrow-in-Furness Division.

BRITISH POST-GRADUATE MEDICAL SCHOOL

As briefly announced in our last issue the Chancellor of the Exchequer will lay the foundation stone of the British Post-Graduate Medical School buildings at the L.C.C. Hospital, in Ducane Road, Hammersmith, on Monday, July 17th, at 4 p.m. This ceremony marks a further stage in bringing into practical operation the scheme recommended by the Post-Graduate Medical Education Committee appointed by Mr. Neville Chamberlain in 1925 and presided over successively by Mr. Chamberlain and Mr. Arthur Greenwood. The scheme is founded upon the association of the new medical school with a public hospital administered by the London County Council. The Government has agreed to contribute a maximum of £100,000 for the building and equipment of the school, and the London County Council, which is co-operating whole-heartedly in the project and without whose assistance the scheme would be impossible of fulfilment, has agreed to incur an equivalent expenditure on such developments and adaptations of the hospital as are found to be necessary at the present time in view of its forthcoming association with the school. The Government has also undertaken to provide in due course for annual grants towards the maintenance of the school as a recognized school of the University of London. The new teaching hospital will doubtless attract medical men from all parts of the world, and especially from the British Dominions and Colonies over-seas, and it should make London one of the chief centres in the world for post-graduate medical training and research. London House, the hall of residence for Dominion students, will enable those fortunate enough to be admitted to it to enjoy the advantages of residential collegiate life. The chairman of the governing body of the school is Sir Austen Chamberlain, who succeeded the late Viscount Chelmsford on the latter's election as Warden of All Souls' College, Oxford.

ANATOMY OF HEADLINES

Writing in praise of Dr. Johnson's real humanity and gentleness of disposition, Boswell said: "I shall never forget the indulgence with which he treated Hodge, his cat." Whether Hodge felt grateful is not known. But editors are often touched by the indulgence of long-suffering readers. Not long ago some sharp things about the illegibility of doctors' handwriting appeared in this column. They might have given offence, but so far only faint chuckling sounds have been heard. From handwriting to headlines is but a short step. Readers occasionally ask whether anything can be done to unload the titles of original articles and clinical memoranda in medical journals. The answer is that much can be done, and is done every week. "Observations upon the Inhibitory Influence of Intravenous Injections of an Aqueous Extract of the Gasserian Ganglion upon the Course of Generalized Gas Gangrene: with Report of One Case: Recovery: Death," has a comprehensive air, and may be (in its author's opinion) a snappy little heading; and yet a stroke or two of the blue pencil will make it more sightly and no less explicit. In former days the headlines of the Annual Meeting papers looked like memorial tablets on cathedral walls, and the change to a simpler form called forth no protests. On the other hand, a title can err on the side of brevity. "Burns" *tout court* may be all very well for a surgical monograph of 800 pages (or for a work of literary criticism), but is perhaps not precise enough at the top of a therapeutic note of 400 words. There are also embarrassing ambiguities which a vigilant sub-editorial eye will detect in time: for example, "Haemorrhoids from the Patient's Point of View." In regard to headlines for letters, we are grateful to the doctor who asked if the recent correspondence on "Genesis of Gallstones" is to be followed by another on "Exodus of Ditto."

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been prepared and will be ready shortly; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1.

CENTENARY OF THE BRISTOL MEDICAL SCHOOL

The centenary of the Bristol Medical School was celebrated by the University of Bristol on June 30th and July 1st. A history of the school, written for this occasion by Dr. George Parker,[1] relates its origin from the fusion of several private schools of anatomy, of which the first was started in 1744, seven years after the opening of the Bristol Infirmary. In 1815 the Society of Apothecaries of London was authorized by Act of Parliament to examine and license all new apothecaries, as the general practitioners were called at that time, and to prosecute unqualified apothecaries. This Act required that candidates for qualification should attend at proper lectures and clinics. The Apothecaries' Society gave "recognition" to some of the lecturers in Bristol as early as 1828, and by 1831 a medical student could attend the whole course in medicine at Bristol, and obtain the licence of the Society of Apothecaries without any period of residence in London. This attitude of the Apothecaries' Society made provincial medical schools possible in England. The College of Surgeons (despite its title, "of England") strenuously opposed the provincial schools, insisting on attendance at a hospital of 100 beds in London or in certain Scottish or Irish medical centres.

Bristol formed in 1833 a very strong school by the combination of lecturers from various groups, urged thereto by Dr. Carrick. He was a Scottish M.D., senior physician at the Infirmary, and a man of great foresight and character. Carrick delivered the inaugural address at the opening of the school on October 14th, 1833. In this address he observed that now for the first time instruction could be given in Bristol in every department of medical science, and he expressed the hope that the medical school would before long form an integral part of the then flourishing "Bristol College," and share in its general literary and scientific training. Soon all the rival schools disappeared, and in 1834 the College of Surgeons was forced to capitulate, offering the same recognition as the Apothecaries had done. Thus the Bristol Medical School was launched on a course which led by various stages to incorporation in the University College (founded in 1876). Ultimately, when the University of Bristol received its Charter in 1909, the old medical school became the Faculty of Medicine in the University. It is this unbroken existence during one hundred years that has just been celebrated. The dean, Professor E. Fawcett, M.D., F.R.S., has occupied the chair of anatomy during forty years of that century, and has been dean of the Medical Faculty since 1906—a record of valued service and unremitting energy that it will be hard to equal.

COMMEMORATIVE FUNCTIONS

The programme of the celebrations was as follows. Friday, June 30th: 3.30 p.m., Receptions at the Royal Infirmary and General Hospital by the respective presidents, Lieut.-Colonel P. G. Robinson, D.S.O., and Miss Hilda Wills; 7.30 p.m., dinner at the University Union under the chairmanship of Professor Fawcett; 9.30 p.m., reception at the University by the Vice-Chancellor, Dr. T. Loveday. Saturday, July 1st: 12 noon, Congregation for the conferment of ordinary and honorary degrees; 1.30 p.m., luncheon at the University Union under the chairmanship of the Vice-Chancellor; 3.30 p.m., garden party given by the Sheriff of Bristol, Dr. W. Kenneth Wills, at the Royal Fort in the University.

The celebrations attracted a large attendance of past and present students; the Lord Mayor and the Sheriff of Bristol, delegates from numerous universities and medical corporations, and many other distinguished guests, honoured the occasion by their presence. Honorary degrees were conferred as follows. *LL.D.*: The Right Hon. Lord Dawson of Penn, President of the Royal College of Physicians of London; Sir Holburt J. Waring, President of the Royal College of Surgeons of England; Sir Norman Walker, M.D., President of the General Medical Council; Sir Frank Colyer, F.R.C.S. *D.Sc.*: Emeritus Professor E. W. Hey Groves, F.R.C.S. *M.D.*: Miles H. Phillips, F.R.C.S., professor of midwifery in the University of Sheffield. Three other honorary degrees will be conferred at a later date, upon Professor G. Elliot Smith, Professor A. V. Hill, and Professor R. Muir, who were unable to be present.

Dr. Parker's centenary history gives an account of the rise and fall of the various earlier schools, and a history, with many illustrations, of the Bristol Medical School from 1833 to 1933. With amazing industry he has included a complete list of students since 1833, with a few lists prior to that date. This work constitutes a notable contribution to the general history of medical education.

The *Bristol Medico-Chirurgical Journal* is fifty years old this year, and according to present plans a special jubilee number will be issued in September, giving a full account of last week's centenary festivities and a survey of Bristol's contributions to medical science in general.

HEALTH OF SCOTLAND

DEPARTMENT'S ANNUAL REPORT

(*Concluded from page 21*)

An encouraging feature of the year's work has been the increased output of houses under State-aided schemes, the number of houses built having risen from 11,056 in 1930, and 10,654 in 1931, to 15,818 in 1932, with a prospect of continued progress in the present year, in view of the fact that the number under construction at the end of 1932 was 19,732. It is pointed out that if an annual output of not fewer than 16,000 houses could be maintained, the shortage in Scotland would be wiped out in a few years. Good progress has been made with the clearance of slums under the 50 per cent. grant provided by the Act of 1923, and 15,349 houses have been constructed under this scheme. There have been certain changes in connexion with the population which have had an important effect upon the housing question. The last census showed that the population of Scotland decreased by 40,000 between 1921 and 1931, but that while the landward population had declined by 90,000, the burghal population had increased by 50,000. Accordingly, to meet the latter increase, some 11,000 new houses may have to be provided in the next ten years in the neighbourhood of the larger burghs. Some 6,100 new houses will be required annually in Scotland. The subsidies paid by the Exchequer during the year 1932 in respect of houses erected by local authorities, private enterprise, etc., amounted to £1,699,404. An important feature of housing has been introduced by the Town and Country Planning (Scotland) Act, 1932, which gives comprehensive powers to local authorities to regard planning schemes as one of their major functions, and empowers the Department to transfer to small burghs powers and duties generally held by county councils. Several schemes have already come into operation, including a large scheme covering an area of some ninety-six square miles in the counties of Aberdeen and Kincardine. Other schemes have been submitted by the burghs of Edinburgh, Glasgow, and Dunfermline, as well as by the Clyde Valley Regional Planning Committee and the Fife Regional Planning Committee.

Sanitation

During the year the Department has approved the details for thirty-one water and drainage schemes intended to provide relief for unemployment, at an estimated cost

of £280,888. Of 114 villages visited, thirty-three water supplies were found to be in need of improvement. The returns for the year have revealed a considerable disparity in the costs for cleansing, estimated per head of the population, as between one local authority and another, and the cost of all services carried out by different cleansing departments has ranged from 11¾d. to 14s. 7d. per head of the population, incineration having proved to be the most costly form of refuse disposal.

Food Supply

A survey of the annual reports of veterinary inspectors has shown that routine inspection of dairy cattle continues to achieve valuable results. The Department holds that true economy is effected by supervision of milk supply at the source with sufficient frequency, and sixteen county councils have now arranged to carry out veterinary inspection three times a year in landward areas, and four times in burghs. As an example of the importance of this matter the experience of Lanarkshire is quoted. This county had 34,000 dairy cows in 1930 and 38,000 in 1931. In the former year, when there was only one inspection, 111 cases of tuberculosis were discovered, while in 1931, when the number of inspections was increased, the cases of tuberculosis discovered rose to 245. It is stated that herds which are recruited entirely by the purchase of cows in the open market are mainly responsible for the presence of tubercle bacilli in milk, and that these herds should be given special attention by more frquent veterinary inspection. The problem of the eradication of bovine tuberculosis has continued to occupy much public and official attention. While the Department believes that only a small proportion of the dairy cattle in Scotland is at any one time capable of infecting the milk supply with tuberculosis, the problem of dissemination of infection through large quantities of milk by mixing one infected cow's milk with hundreds of gallons of pure milk, is a difficulty inherent in the modern system of distribution in cities. An investigation into the prevalence of tubercle bacilli in milk has been carried out, and the general rate of infection of milk retailed in Edinburgh, Glasgow, Dundee, and Aberdeen has been found to be a little over 5 per cent. ; the examination of a large number of samples of certified and Grade A (T.T.) milks has shown these milks to be safe. The number of herds licensed for the supply of certified milk has risen from forty-four in 1927 to eighty-seven in 1931, while that for the supply of Grade A (T.T.) milk has risen from fifty to ninety-two in the same period. There are at least eighty-five other tubercle-free dairy herds in the country, although the owners hesitate to bring them under the grading system owing to the limited demand for tubercle-free milk. It is suggested that a substantially increased demand for this milk would do more than any other single measure to eradicate tuberculosis from dairy herds. Only two education authorities—in Edinburgh and Aberdeen—have made use of the powers of the Education (Scotland) Act, 1930, to incur expenditure in supplying milk to children attending schools within their areas. With regard to meat supply it is pointed out that, owing to the low prices obtainable for live stock, many farmers have undertaken the killing of their animals and the retail of meat, and that the entry of farmers into the meat trade has given rise to difficulties in connexion with abattoirs. Amendment regulations have recently been published in draft, requiring that, in future, imports of beef and mutton shall be accompanied by a veterinary surgeon's certificate of freedom from disease. It is hoped that the necessary arrangements with the Governments of exporting countries will be completed in time to permit of the new requirements coming into force during 1933. Samples taken during the year under the Food and Drugs (Adulteration) Act, 1928, totalled 16,402, of which 7,680 were formal and 8,722 test samples. During the year there have been several small outbreaks of food infection due to pathogenic organisms of the enteric group, and one of an outbreak of milk-borne scarlet fever. Attention is drawn to the fact that some cases of illness may be due to strains of staphylococci, as well as to organisms of the enteric group.

SERUM TREATMENT OF POLIOMYELITIS

SUPPLIES FOR THE LONDON AREA

The Medical Research Council announces that, after discussion with the Ministry of Health, the Public Health Department of the London County Council, and the Lister Institute, it has been decided to issue a supply of serum obtained from patients convalescent from acute poliomyelitis, with a view to its trial in the treatment of the pre-paralytic stage of the disease.

Encouraging reports on the results obtained by this treatment have been received from Australia and Canada, but adequate data are still needed to confirm its value, particularly in view of doubts which recent experience in America has cast on the reliability of the basic data.

With the co-operation of several hospitals a limited supply of " convalescent " serum has already been obtained and prepared for issue at the Lister Institute, Elstree, Herts. The main stock of this serum has been deposited at the Western Fever Hospital, Seagrave Road, London, S.W.6 (telephone, Fulham 2105), where suspected early cases will be admitted for observation and treatment in the pre-paralytic stage, and whence supplies of serum may be obtained by other hospitals and practitioners in the London area for use in appropriate cases. When the quantity of available serum is larger it is hoped also to be able to send supplies to different university centres for issue on demand in the provinces.

The serum will be supplied gratuitously on the understanding that the case-record forms enclosed in the cartons shall be completed and sent for collation and analysis to the Medical Research Council, 38, Old Queen Street, S.W.1. Full particulars as to mode of administration and dosage are contained in the cartons. It is essential that the administration of the serum should only be done by a medical practitioner or pathologist who is experienced in the technique of lumbar puncture and intrathecal injection. The serum is issued in outfits each containing four 25 c.cm. ampoules, or sufficient serum to complete the treatment of a single case.

Owing to the limited stock of serum at present available it is particularly requested that the treatment shall be used only in the *pre-paralytic stage of the illness*, or exceptionally in a pyrexial phase when the symptoms indicate a rapidly progressive invasion of the spinal cord as shown by extension of the paresis or paralysis. The serum should on no account be used in the post-febrile stage when the infection has become quiescent and paralysis is established: the evidence does not support its employment in this stage.

The attention of physicians using this serum is called especially to the *Memorandum on Acute Poliomyelitis*, issued in 1932 by the Ministry of Health (London, H.M. Stationery Office, price 2d. net).

With a view to increasing the stock of " convalescent " serum for use during the approaching season, practitioners and public health officers who know of convalescents, or groups of convalescents, willing to be bled are earnestly requested to communicate with the Lister Institute, Elstree, Herts. Arrangements could then be made to supply apparatus for the collection of serum, or, if circumstances permitted, to send a worker to perform the actual bleeding.

The tenth annual report of the *Journal of the American Medical Association* (May 20th) on the diphtheria mortality in the ninety-three cities in the United States with a population of more than 100,000, shows that the diphtheria death rate per 100,000 of population in 1932 ranged from 8.16 in the case of the West South Central States to 2.53 in the Middle Atlantic States. Five cities did not register a single death from diphtheria in 1932. New York, for the third year in succession, reported a very low rate (2.9 per 100,000), Philadelphia had the best record (0.8) for any American city with a population of more than a million. The city of Camden had the highest rate (8.4), as it had in 1931.

insurance should be something more than mere payment when a person was sick. It should attempt to improve the health of the country as a whole, and particularly of the class which came under the insurance. It should be co-ordinated with the public health system of the country. The present Bill would create an extremely powerful body whose duty it would be to carry out only one part of the health work of the country without contact at all with the other health activities. The societies had never concerned themselves very much with the health of their members; they had contented themselves with the provision of benefit. The Government would be able to exercise greater supervision at lower cost over one society than over sixty-five small societies. There was a danger, however, that one big society might interfere in political matters and try a political "pull." It would be powerful and effective, possibly in a dangerous way. With regard to certification, he did not question that evidence of laxity and remissness in the issue of certificates could be obtained. It was not, however, representative of the present system as a whole. Mr. S. T. O'Kelly, Minister for Local Government and Public Health, said that they were attempting to deal with a crisis that was threatening in national health insurance. When he came into office he was advised by the officials of the Department, who had had long experience of insurance, that a Bill of this nature was urgent. The danger was that if they did not tackle the problem in this way there might be reduced benefits. They thought it would be equitable to bring all the insured persons into one society, sharing credits and losses all over. Senator Dowdall said there was a consensus of opinion that unemployment caused the greater drain on benefits. It had been suggested that this was due to lax certification. He himself thought that a medical officer was entitled to give a certificate on borderline cases. The Minister replied that that was a matter for the conscience of the doctor, and he believed that the mass of medical men were humanitarian. Personally, his inclination would be to act generously, but as Minister he would be bound by the law.

England and Wales

Mental Welfare

The report on the conference on mental welfare, which was held last December in British Medical Association House, has now been issued in booklet form by the Central Association for Mental Welfare (24, Buckingham Palace Road, S.W.1), price 3s. 6d. It contains the addresses delivered on that occasion, together with a verbatim report of the discussion following each paper. The main topics dealt with were: the family care of mental patients; the scope and possibilities of home training; the social control of feeble-minded children leaving the elementary schools; inheritance, with special reference to mental inheritance; the value of family histories in the study of inheritance; and school retardation as a factor in certain conduct problems of childhood and adolescence. The volume has a definite value in that it represents the focusing of very different points of view on certain problems of mental welfare, both as regards their aetiology and their treatment. One conclusion which emerges clearly is that in this department of medical practice, as in others, early accurate diagnosis, combined with the essential treatment of the causes of the morbidity, rather than of the symptomatology, opens the way to a substantial programme of prophylaxis as well as to the relief of suffering. Sir Henry Brackenbury emphasized the importance of recognizing in this connexion the biological facts concerned, which he insisted were far too often overlooked. Even where cure was apparently unlikely there was much that could be done to alleviate the condition, and the requirements of financial economy should not be allowed to shelve the problem of mental deficiency as one of relatively little significance. The whole report is an effective championship of this point of view.

London's Hills of Refuse

Speaking on June 30th at a luncheon of the Advisory Committee on London Refuse, the Minister of Health said that, without being an alarmist, he must strike a warning note about the ranges of hills of refuse which were being accumulated on the outskirts of London at the rate of about a million tons a year. Unless the work was properly done, these hills of refuse would become a sanitary danger. In the past the work had not been properly done in all cases; he could not say that it was being properly done in all cases even now. There was still room for improvement, and improvement there must be for the sake of the public health. There was also room for improvement in the methods of collection of refuse. The standards of some authorities were not in this matter equal to the best. These were matters of first importance for the health of London. The primary responsibility was with the twenty-eight metropolitan boroughs and the City Corporation, and they had to co-ordinate their work with the authorities of the districts round London where the refuse was tipped. Most certainly some co-ordinating authority was necessary to act as a meeting place for consultation and a clearing-house for information. At his suggestion the present committee had been formed, representing the twenty-eight metropolitan boroughs and the Corporation of London. The hope and intention was that by means of this committee the necessary improvements in method could be achieved by voluntary co-operation. It was far better that it should be done voluntarily than that they should be obliged to have resort to compulsory powers, with the attendant need for fresh legislation. The committee had made a beginning with its important task, and he wished it all success.

L.C.C. Consultants and Specialists

In March last the London County Council approved revised arrangements for the provision of a consultant and specialist service for hospitals and institutions under its management. Certain additional and contingent matters were brought before the Council at its meeting on June 27th. As from July 1st, 1933, and subject to review at the end of a year, the tuberculosis officers of the metropolitan boroughs are to be deemed honorary consultants for tuberculosis in the general hospitals under the Council's management. The normal number of sessions to be worked by orthopaedists at grouped general hospitals and institutions is to be reduced by one (that is, from 11 to 10). The plastic surgeon and the assistant plastic surgeon at Hammersmith Hospital are to be placed on the scale of salary for consultants, which will mean a slight increase in their remuneration. The anaesthetists who are called upon to work at the plastic surgery unit at Hammersmith are to be paid at the rate of two guineas for a session of approximately two and a half hours' duration. A consultant for venereal diseases is to be appointed at St. Stephen's and St. Charles's Hospitals, attending three sessions a week at the former and one session a week at the latter. The position of orthopaedic surgeon at Queen Mary's Hospital for Children, Carshalton, will entail two sessions a fortnight—the surgeon to be available as required for work in the appropriate group of general hospitals—and the salary will be 200 guineas a year, with meals on duty. The position of consulting thoracic surgeon at King George V Sanatorium, with which are grouped Pinewood Sanatorium and High Wood

Hospital for Children, requires attendance at seventy-eight sessions a year, and the fee is six guineas a session, with first-class railway fare. The position of ear, nose, and throat surgeon at these same institutions entails 120 sessions a year, with the same sessional fee. The position of consulting thoracic surgeon and of ear, nose, and throat surgeon at certain in-London hospitals is remunerated at three guineas a session, or in some cases £150 a year for one session a week. At St. Luke's Hospital, Lowestoft, which is also an L.C.C. institution, the position of orthopaedic surgeon will entail one visit a month and other visits as required, the salary to be £105 a year and travelling expenses, while the consulting surgeon at the same institution, who will visit as required, is to receive two guineas for a consultation, or three guineas for an operation, including consultation. It is also proposed to the Council that during the absence of a specialist or consultant owing to sickness or other cause he should provide at his own expense an approved deputy, or, alternatively, that the Council should provide a deputy, in which case the pay of the regular consultant would cease during the period of absence. Consultants and specialists who have been appointed as from July 1st have been informed of this arrangement.

Physical Exercises in Child Education

A very convincing demonstration of what physical education can accomplish in the muscular and mental development of boys and girls and as a preparation for athletics was afforded recently at the Savoy Theatre in London by Miss Margaret Morris, whose name has been associated for many years with dances and other physical activities which combine the hygienic and artistic values of movement. The exhibition was given under the patronage of many distinguished persons, including Lord and Lady Dawson of Penn and a number of leading surgeons and orthopaedists. Children from fourteen schools participated, including girls' high schools, preparatory schools for boys, and certain special L.C.C. schools, one of them for tuberculous children. Girls from the Heritage Craft School for Cripples, at Chailey, in Sussex, also contributed some exercises which were adapted to provide as far as possible normal movements for the physically defective. But the greater part of the demonstration was undertaken with normal children, for whom the exercises were a part of their ordinary education. Miss Margaret Morris, in describing her methods, explained that the exercises were carefully graded and chosen to suit each individual, so that any faults of posture, to which ill-health was often due, or any particular weakness might be overcome. At the same time the exercises were interesting to perform because they were all compositions in movment, developing a natural grace through balance and muscular control, and seeking to maintain or establish health through artistic and rhythmical means. A prominent educationist, Mr. Roger Raven, vice-principal of Goldsmith College, University of London, said a few words on the place of physical training in education, and referred especially to the power of children to create movement for themselves. He praised Miss Morris's methods because, although some general instruction was given, the music itself told the child what to do, much of the graceful posture and movement being spontaneous—the reaction of the child to the inspiration of the music. He emphasized also the value of the group in all these exercises, saying that no child properly grew up alone, and that the group or team was as essential to aesthetic grace as to achievement in sport. Mr. R. C. Elmslie also spoke briefly on the correction of minor defects by normal exercises and the value of an approximately normal exercise for children suffering from physical maladjustment. He wanted to make it plain to the public that physical education was not a stunt, and, further, that it was not a question merely of developing muscle, but that the training reacted on the vital organs and, indeed, on all the faculties, mental and physical. The aim of the teacher, like the aim of Ling himself, the pioneer of Swedish medical gymnastics, was to secure movements which were at once simple, interesting, and intelligent. The Margaret Morris movements, he said, were scientifically thought out and easily taught, and in a quiet way much clumsiness and lack of symmetry could be overcome.

Progress at the London Hospital

In the course of his annual report at the prize-giving ceremony last week, Professor William Wright, dean of the London Hospital Medical College, mentioned the formation within the hospital of two additional special departments, which will deal respectively with diseases of the heart and with brain surgery. Progress in these two branches of medicine had been so great, technical methods of examination and treatment had become so elaborate, that it was judged necessary to create these departments if one of the primary purposes of a large medical school was to be fulfilled satisfactorily—the extension of knowledge. Fortunately the London Hospital was so large that, despite the formation of these departments, there would remain ample clinical facilities for that other great purpose—the education of students in routine methods of diagnosis and treatment. These changes would result in certain additions being made to the honorary staff. In recent months they had been able to make various structural alterations in the college, providing in particular a new and well-equipped histological laboratory—an improvement rendered possible by a legacy under the will of the late Dr. Ewan Frazer. During the year the Students' Hostel Appeal Committee, mainly through the energy and enthusiasm of Mr. Lett, succeeded in obtaining a promise of an admirable site from the house committee, and in raising £15,000 among members of the house committee and of the hospital and college staffs. The services of a distinguished architect had been engaged, and the offer of a loan of £10,000 on favourable terms had been received; but the problem of raising at least a further £5,000 remained.

Extension of Maudsley Hospital

A scheme of extension for Maudsley Hospital has been approved by the London County Council, providing for a new and larger out-patient department and special treatment block, a children's out-patient department, additional accommodation for ninety-six patients, a small isolation wing, a nurses' home to accommodate sixty nurses, and an enlargement of the central pathological laboratory. The Maudsley Hospital was opened ten years ago for the reception of early cases of mental disorder, and is now reserved entirely for voluntary patients received under the provisions of the Mental Treatment Act, 1930. It has accommodation for 207 in-patients, and a ward in King's College Hospital, which for the time being is rented as an annexe to Maudsley, accommodates thirty-five more. Increasing demand for treatment at the hospital and difficulty in meeting the needs of a steadily growing out-patient department have pointed to the necessity for enlargement, and three years ago a capital estimate of £22,000 was approved in respect of the acquisition of land for this purpose. The total estimated cost of the scheme for extension, including equipment, is £121,500. It is proposed to carry out the work in sections, the first section to consist of the new out-patient department and special treatment block.

Hernia and Appendicectomy

SIR,—Recent correspondence in your columns on the association of inguinal hernia with the muscle splitting incision for appendicitis induces me to put forward a theory which I have held for some time to account for the occasional appearance of inguinal hernia after the removal of an appendix by the McBurney incision.

It seems to me to be insufficiently known that patients will complain of pain, usually of a stabbing nature, referred to the area above the inguinal ligament some time—occasionally months—before the appearance of a hernia. The type of case I am thinking of is that of a patient who is putting on fat. Attempts on the part of the swollen omentum to force its way into the mouth of a pre-existing sac after some unusual effort will give rise to pain which may be mistaken for appendicular pain. The appendix is removed, and some time later an inguinal hernia makes its appearance. Many surgeons like to use the muscle-splitting incision for so-called interval appendixes, although it is in precisely these cases where there is an element of doubt that it ought not to be used.

I should like to ask those who regard an injury to the ilio-inguinal nerve as the cause, how many times they see this nerve in the McBurney operation, and why no one seems to have recorded a left inguinal hernia following the use of a similar incision on the left side for a colostomy.—I am, etc.,

Capetown, May 23rd GEORGE SACKS, M.B., F.R.C.S.

The Word "Spontaneous"

SIR,—Is it not high time that writers on medical and scientific matters discarded that objectionable—because misleading—word "spontaneous"? It is either slackness of thought or an over-rigid adherence to routine that keeps such a word alive in any scientific connotation. A process cannot, strictly speaking, be spontaneous—that is, self-caused. It can but be the effect of a prior cause, and therefore the word is really masquerading under the guise of an assurance of an impossible state of affairs, to conceal ignorance of the *primum mobile* of the process in question. By all means concede to the lay press the right to use such expressions as "a spontaneous gift," or "a spontaneous burst of applause," despite their intrinsic incongruities, but such licence is unpardonable in science.

Biologists are constantly using the word "spontaneous" in relation to motion, action, growth, variation, generation, etc., chemists talk of the spontaneous combustion of coal or oil, physicists of the spontaneous disintegration of radio-active matter, while medical men have their spontaneous recoveries and fractures, and the spontaneous rectification, version, evolution, and expulsion of the foetus. In to-day's *British Medical Journal* are two headlines in the *Epitome of Current Medical Literature*, "Spontaneous Subarachnoid Haemorrhage" and "Spontaneous Serum Sickness." *Hinc illae lacrimae!*—I am, etc.,

CHARLES M. BEADNELL,
Ringwood, June 24th Surgeon Rear-Admiral

*** Loath to steal a march on others, whose feelings about the word 'spontaneous" may be stronger than our own, we must, however, point out (1) that in the original article of which an abstract appeared in the *Epitome* under the heading of "Spontaneous Subarachnoid Haemorrhage" the author states "By using the word 'spontaneous' I wish to exclude all traumatic cases", (2) that the second abstract, headed "Spontaneous Serum Sickness," describes two cases in which symptoms arose from the absorption of a tuberculous effusion—that is, *without the administration of serum*, and in the absence of any outside agency. It remains for us to quote the *Oxford Dictionary*, which defines spontaneous as "occurring without apparent external cause, having a self-contained cause or origin."

Arthritis and Allied Conditions

SIR,—The main object of the report of the Arthritis Committee, published in the *Journal* of June 17th, is, in the words of your leading article, 'to present to the practitioner an authoritative statement on the subject of arthritis which may serve him as a guide amongst the shoals or conflicting theories and the enthusiastic assertions of the advocates of panaceas.' This is a truly admirable object. It was a difficult one, and it is apparent from the report that this difficulty has been quite insurmountable. As medical practitioners in general and in specialized spheres we are seeking guidance as to the lines along which attacks against rheumatism are to be directed. Much information has been brought to us but we are not in a position to decide what of it is of essential, or immediate, or of possible later value. The present authoritative statement suggests little hope for an organized advance, but rather indicates a prospect of disorderly retreat. There is no wide survey of the situation giving indication where to advance, to entrench, or to retreat.

In the first paragraph, on nomenclature and classification, it is stated that subacute rheumatism, specific infections such as gonococcal, and gout have been excluded from the scope of this inquiry. The section opens with rheumatoid arthritis, "primary" and "secondary." As a clinical grouping surely this is unorthodox and unwise. Some thirty years ago Sir William Hale White drew a brilliant clinical picture which in its colour and detail is as perfect to-day, and is one which gives pleasure to those of us who are students of this subject. The clinical features of primary and secondary rheumatoid arthritis, as detailed in this report, are seemingly identical, and in the experience of some of us are present in many cases in which there is clinical, bacteriological, and radiological evidence of gout or gonococcal infection. The clinical picture that we recognize is taken away, and one that is unknown to us, and the accuracy of which we doubt, is put in its place. It is the discriminating selection of facts, as distinguished from supposed facts and fiction often associated with the diagnosis and treatment of the various stages of the rheumatic diseases, that it is the purpose of a report such as this to present. This is absent, and in its place are static pictures of worn-out diseases and lists of remedies cited with little or no indication of their place and significance in the various pictures to which they refer.

In regard to treatment, the first section following the short opening paragraph on prophylaxis is a section on vaccines (p. 1044), and the methods of treatment by vaccines and intrapelvic diathermy take an important place. In the former no indication of the type of case suitable for this treatment is given, and in the latter successful results referred to occurred in conditions such as gonococcal infection, which are admitted as being *outside the scope of this report*.

No vivid pictures of at least certain recognizable forms of arthritis are drawn and their treatment detailed. Methods of treatment which in their specific place are invaluable are, without definite reference or warning as to their limitations, allowed to usurp the place of principles and proven facts. A biased and distorted picture has been given which, if at all understandable is one that may well increase rather than diminish the difficulties of the practitioner. Within recent years much work has been done, new facts on diagnosis and treatment have been revealed, but as yet they have not been brought to the knowledge of the majority of medical practitioners.

CORRESPONDENCE

The B.M.A. Nutrition Committee

SIR,—I hope a strictly practical report may be aimed at. It is idle, as it seems to me, to imagine that an exhaustive report is possible in time for the necessary action to be taken. *Malnutrition* is widespread (in spite of statistics to the contrary) among both children and adults. An "academic" committee may lack the necessary criterion of "normality." An inquiry among selected general practitioners and welfare nurses and others actually in daily touch with the problem might produce reliable and useful information. For my part, I consider a rapid voluntary "social survey" undertaken in "typical areas" would gain in depth and precision what it might lack in academic perfection and in comprehensiveness. Naturally its results should be "criticized" by an "expert" team of experienced scientists.—I am, etc.,

Redditch, July 3rd. HOWARD E. COLLIER.

Medical Practice and the Curriculum

SIR,—I am much interested in the suggestions given by Sir Ernest Graham-Little (June 24th, p. 1124) for the reform of the medical curriculum. The continuous increase in the range of matter with which acquaintanceship is required is a process that must of urgent necessity be brought to an end in the near future. The problem is admittedly one of very great difficulty, but there seem to be some reasons for believing that insufficient search is being made in other directions than that merely of a revision of the curriculum, however independently desirable such revision may be; and that relatively too much attention is being paid to the preparation for practice and too little attention to the conditions of practice itself. The science and art of Medicine, using the word in its widest sense, is expanding at least as rapidly now as at any period in its history, and there is no reason to anticipate any early check to this accumulation of new knowledge and new disciplines. This progress, moreover, can neither be ignored nor, under existing systems, can it be adequately assimilated.

It may well be that the time has come to recognize that *general* practice has had its day, and that specialism for all, as wide as possible, but still specialism, is the only satisfactory solution. General practitioners must become either physicians or surgeons, and confine their work either to medicine (in its restricted sense) or to surgery (midwifery for this purpose falling, presumably, within the province of the surgeon), for in no other way will it be possible for even the most gifted to maintain that standard of knowledge and resource that has been achieved in the past. That there are grave objections in principle as well as serious practical difficulties to a thorough-going dichotomy such as this cannot be denied, but the apparently increasing number of partnerships of physicians and surgeons, especially in the larger towns, seems to suggest that such a scheme may be already on its way. At the present time any practitioner may, of course, restrict his practice or not in any way he may choose, but I contemplate a system under which such restriction will be virtually compulsory, and in which some knowledge of all branches of Medicine will give place to a fuller experience of fewer branches.

If such a system were universally adopted the final qualifying examinations could no doubt be modified in important particulars, for it might be possible either to allow candidates the choice of a more simple examination in medicine and its associated subjects, with a more searching test in surgery and its branches, or to allow the alternative combination to those intending to practise as physicians.

A modified form of comprehensive "specialism" such as I am suggesting, though it would doubtless stimulate the formation of partnerships, would by no means, I think, imply the elimination of the independent practitioner, though perhaps one of the greatest difficulties would be to persuade the public to co-operate in a scheme that would virtually have the effect of causing every patient to require two regular doctors; but such prejudices are probably not insuperable. Serious as the obstacles undoubtedly are to any such division of labour in medical practice, I feel that reform on some lines of this sort is the only possible solution if the highest standards of diagnosis and treatment are to remain available for all.—I am, etc.,

London, W.8, June 26th. ANTHONY W. CAMAC MELLOR.

Cortical Extract in Addison's Disease

SIR,—In the course of a leading article on "The Suprarenal Cortex" in the *Journal* of June 10th you state that treatment of Addison's disease with cortical extract "fails to remove three cardinal features of the disease—namely, hypotension, pigmentation, and hypoglycaemia." It seems to me that, so far as the hypotension and pigmentation are concerned, this statement is contrary to the bulk of the evidence. Levy Simpson[1] describes a series of six cases, all of which showed a diminution of pigmentation following treatment with cortical extract. Four of these cases also showed a definite rise in blood pressure. In their account of twenty cases treated with cortical extract, Rowntree et al.[2] state that a decrease in pigmentation was one of the effects noted, and also a rise of blood pressure in those patients who were in a state of crisis when treatment began. Unfortunately details of these changes are given in only a few of the case reports. In one of the three cases described by Benham et al.[3] a rise of blood pressure occurred following administration of cortical extract. In the case described by McCrie et al.[4] a rise in blood pressure and a decrease in pigmentation were observed. The same is true of the case described by Thompson and Russell.[5]

The evidence for the effect of cortical extract on the hypoglycaemia of Addison's disease appears to me to be too meagre as yet to permit of a conclusion either way.—I am, etc.,

Oxford, June 26th. MARY FISHER.

Treatment of Combined Sclerosis

SIR,—Dr. William Sargant (July 1st, p. 34) is perfectly right in pointing out that my patient who developed megalocytosis and subacute combined degeneration while under treatment with iron was having a good deal less iron than he advises. I am much interested in Dr. Sargant's work on subacute combined degeneration, which seems to me a most promising research on this very obscure malady. But when there are several remedies for a disease there is a risk that the inexperienced may employ none of them to the best advantage. For this reason I stressed the value of desiccated stomach to the general practitioner in the treatment of pernicious anaemia and subacute combined degeneration, as it is a cheap and complete remedy, whereas iron is apparently of little or no value for the anaemia.—I am, etc.,

London, W.1, July 3rd. L. J. WITTS.

Hernia and Appendicectomy

SIR,—Recent correspondence in your columns on the association of inguinal hernia with the muscle splitting incision for appendicitis induces me to put forward a theory which I have held for some time to account for the occasional appearance of inguinal hernia after the removal of an appendix by the McBurney incision.

It remains for us to quote the *Oxford Dictionary*, which defines "spontaneous" as "occurring without apparent external cause, having a self-contained cause or origin."

Arthritis and Allied Conditions

SIR,—The main object of the report of the Arthritis Committee, published in the *Journal* of June 17th is, in the words of your leading article, to present to the practitioner an authoritative statement on the subject of arthritis which may serve him as a guide amongst the shoals of conflicting theories and the enthusiastic assertions of the advocates of panaceas." This is a truly admirable object. It was a difficult one, and it is apparent from the report that this difficulty has been quite insurmountable. As medical practitioners in general and in specialized spheres we are seeking guidance as to the lines along which attacks against rheumatism are to be directed. Much information has been brought to us, but we are not in a position to decide what of it is of essential, or immediate, or of possible later value. The present authoritative statement suggests little hope for an organized advance, but rather indicates a prospect of disorderly retreat. There is no wide survey of the situation giving indication where to advance, to entrench, or to retreat.

In the first paragraph, on nomenclature and classification, it is stated that subacute rheumatism, specific infections such as gonococcal, and gout have been excluded from the scope of this inquiry. The section opens with rheumatoid arthritis, "primary" and "secondary." As a clinical grouping surely this is unorthodox and unwise. Some thirty years ago Sir William Hale White drew a brilliant clinical picture which in its colour and detail is as perfect to-day, and is one which gives pleasure to those of us who are students of this subject. The clinical features of primary and secondary rheumatoid arthritis, as detailed in this report, are seemingly identical, and in the experience of some of us are present in many cases in which there is clinical, bacteriological, and radiological evidence of gout or gonococcal infection. The clinical picture that we recognize is taken away, and one that is unknown to us, and the accuracy of which we doubt, is put in its place. It is the discriminating selection of facts, as distinguished from supposed facts and fiction often associated with the diagnosis and treatment of the various stages of the rheumatic diseases, that it is the purpose of a report such as *this to present*. This is absent, and in its place are static pictures of worn-out diseases and lists of remedies cited with little or no indication of their place and significance in the various pictures to which they refer.

In regard to treatment, the first section following the short opening paragraph on prophylaxis is a section on vaccines (p. 1044), and the methods of treatment by vaccines and intrapelvic diathermy take an important place. In the former no indication of the type of case suitable for this treatment is given, and in the latter successful results referred to occurred in conditions such as gonococcal infection, which are admitted as being outside the scope of this report.

No vivid pictures of at least certain recognizable forms of arthritis are drawn and their treatment detailed. Methods of treatment which in their specific sphere are invaluable are, without definite reference or warning as to their limitations, allowed *to usurp* the place of principles and proven facts. A biased and distorted picture has been given which, if at all understandable is one that may well increase rather than diminish *the difficulties* of the practitioner. Within recent years much work has been done, new facts on diagnosis and treatment have been revealed, but as yet they have not been brought to the knowledge of the majority of medical practitioners

When they have been assimilated and their relative values assessed, the early diagnosis and successful treatment of the rheumatic diseases will be more frequent. The present opportunity which has been offered to do this does not appear to have been taken. It is my sincere wish and belief that this report will in part achieve its excellent purpose by arousing interest and encouraging a critical attitude and a desire and demand for knowledge in those of us to whom it is addressed.—I am, etc.,

London, W.1, June 27th. FRANCIS BACH, M.D.

Cosmetics

SIR,—When I contributed an article on cosmetics to your issue of June 10th (p. 999) I little realized that it would bring not only the public Press and its readers about my head, but also the more Olympian thunder of Dr. MacKenna, who unkindly accuses me of being on the one hand provocative and on the other insinuating. He rebukes me first for having entirely failed to acknowledge the assistance his paper was to mine. My bibliography comprised twenty-eight references, Dr. MacKenna's included. If I had made individual acknowledgement of what I owed to each of these it could only have been done by sacrificing a considerable part of my paper, which was already too long and had to be cut down. This would, perhaps, have been no great loss, but one has an affection for one's offspring of the pen and a dislike of mutilating them. I see now that it would have been wiser and less "provocative" to have amputated my infant's legs and supplied it instead with a sound genealogical tree. I apologize to Dr. MacKenna and to the other twenty-seven authors for having failed to do so.

Dr. MacKenna goes on to say that "by making full use of fragmentary excerpts torn from their context she attributes to me a bias which is, I think, undeserved." In criticizing an article, unless one quotes it in its entirety—which is manifestly impossible—one is always open to this charge of literary assault. But in order to satisfy myself that I had not inadvertently misquoted Dr. MacKenna I have carefully re-read his original article, and it appears to me that my interpretation of it was scrupulously fair, and this, I cannot but think, must be the opinion of any unprejudiced reader. Space, and the patience of your readers, forbids my taking up every point. I will therefore confine myself to two examples. Dr. MacKenna says: "I am not, as Dr. Carleton insinuates, unaware that dirt may be removed with cold cream." What I said was: "MacKenna ridicules the cleansing properties of cold cream." But is this not the natural inference of his statement: "The majority of 'beauty specialists' suggest that soap and water should not be used, but the face should be 'cleansed' [*sic*] by the application of cold cream"? The *sic* is Dr. MacKenna's, not mine. Later he says: "I object to being classified by insinuation as a person who condemns cosmetics as wholly injurious." "On the whole, injurious," would have been more correct, and for this slip I do apologize. But may I, in my turn, deprecate the use of that word "insinuation"? "Implication" or "inference"—Yes; but not "insinuation." "*Des coups d'épée, Monsieur, pas des coups d'épingle.*"

The final sentence of Dr. MacKenna's letter appears to me to sum up our grounds of difference. "The windmill," he says, "against which I have tilted is the continuous use of cosmetic preparations—the endless application of astringent lotions and fatty and waxy ointments to the detriment of the individual and the very definite benefit of numerous commercial interests." With regard to the astringent lotions I am, as I said in my paper, in substantial agreement with his view. The benefit of commercial interests is irrelevant to the point at issue, except as a red herring of doubtful flavour. There remain the ointments. And here I can only humbly suggest that Dr. MacKenna, like Don Quixote, may be mistaken in his windmill. The women of my practice or acquaintance who for years have used cosmetics appear to me, *on the whole*, to have better-looking skins than those who do not. This is, of course, a crude and superficial observation, and many other factors obviously enter into the matter. But at least these women do not appear to have suffered as a consequence. Since I can find neither the blocking of the sebaceous glands nor the atrophy to which Dr. MacKenna refers, what can I do but invoke St. Thomas and repeat, "Show me the proof"? Dr. MacKenna's skill and experience are so much superior to mine that I should hesitate to express views contrary to his if I were not comforted by the fact that they are sanctioned, as I said in my article, by such authorities as Kromayer in Germany and Sabouraud in France. So that in dermatology, as in other matters, what is heresy in England is orthodoxy abroad.—I am, etc.,

Oxford, June 27th. ALICE CARLETON.

Treatment of Chorea

SIR,—In the *Journal* of June 10th (p. 1003) Dr. Donald Bateman, in his short paper entitled "A Treatment of Sydenham's Chorea," advocates the induction of fever by the use of injections of the triple typhoid vaccine, giving a detailed description of the routine practised at the Bellevue Hospital, New York. He advances as his reason for utilizing this drastic therapeutic measure that it shortens by more than 50 per cent. the duration of the patient's stay in hospital. During the last two or three years I have given trial to this form of non-specific therapy in treating cases of chorea, but I do not find that it shortens the stay of the patient in hospital, for the wasting and weakness consequent on the induced hyperpyrexia render it incumbent to keep the patient as a convalescent for some weeks before sending it back to an environment which all too often is unhygienic and also not conducive to that requisite rest and quiet that cases of chorea need. Again, I have not noticed that this form of therapy diminishes recurrences, but, on the other hand, I am inclined to think that the recurrence, when it happens is often more violent than in the case of those treated by the usual rest and therapeutic method. My cases are too few to be dogmatic on this point.

During the last twenty years, in the treatment of chorea, I have tried, I should imagine, every drug that has been advocated, from arsenic to nirvanol, and every method of therapy—hydrotherapy, psychotherapy, etc.—and I still wait to find a drug or treatment which will shorten the duration of this mild but important disease. The most dramatic sudden cures of chorea I have ever seen occurred in two cases in which erysipelas intervened—an interesting line of thought, remembering the possibility of the streptococcus as a causal factor. In four cases which I treated some years ago by the withdrawal of blood from the patient and the injection of the serum intrathecally, the results were also dramatic—hyperpyrexia, and after two injections a cessation of choreic movements; but just as I was becoming enthusiastic they all relapsed—relapsed badly—and one patient still attends my clinic, though her original treatment took place five years ago.

My object in writing this letter is to sound a note of warning in the general adoption of a line of treatment, especially outside hospitals, in which the end-results, in my opinion, are not justified by the attendant discomfort and danger.—I am, etc.,

LEOPOLD MANDEL, M.D., M.R.C.P.
Physician, with Charge of Children's Department, London Jewish Hospital.

London, W.1, June 22nd.

"New Treatments for Old"

SIR,—I read Lord Horder's Oration on the above subject with great interest, and, it must be confessed, with some disappointment.

I was interested to note the reference to the Abrams box —" a piece of machinery (save the mark!) "—" apparatus " would have been a more appropriate word—which offends both physical and physiological principles. There are few of us who would differ from Lord Horder's remarks on that subject. It will be remembered that he presided over the committee which investigated the alleged claims of that egregious piece of humbug ; and that there was a disposition on the part of some members of the committee to think there might be something in it.

Lord Horder very rightly deplores slovenliness " on the point of terms and definitions," yet shortly afterwards remarks that " it is Nature that cures, not we." There are some who wonder whether Nature ever really does cure or whether she merely " effects repair "—a very different matter, which necessarily depends on the nature and extent of the lesion. It would not be incorrect to say that the surgeon " cures " a hernia, but that Nature effects the repair. If a " disease process " can be arrested by the application of physiological, pathological, and therapeutic knowledge, Nature may usually be depended upon to bring about repair, but not necessarily to cure.

I notice that Lord Horder refers to the appeal to a credulous public made by what he terms " direct action " remedies—" blood mixture," " asthma cure," etc. He might preferably have called them " selective action " remedies. Even preparations used by the profession do not escape the lash of his whip. After all, What *is* in a name? I for one shall always feel grateful to one of the remedies he mentions—namely, antibacsyn. Influenza may differ from furunculosis as far as outward manifestations are concerned, but is there no resemblance immunologically, if I may use such a word without offence?

Lord Horder mentions an intestinal disinfectant which will render the faeces sterile. I know the one to which he probably refers, and have used it and been thankful for it—and so have others who have worked in the Tropics. There was no need for my imagination to " toy with what might happen to a patient with sterile faeces." My patients' faeces only remained sterile as long as I wanted them to do so ; and they recovered. It is always an advantage for patients to recover. Even Lord Horder admits that an effective intestinal disinfectant is a " consummation devoutly to be wished by many." After all, it assists Nature to effect repair. Nobody with an elementary knowledge of the physiology of digestion would contemplate the maintenance of permanent sterility of the alimentary canal.

If there is a lesson in Lord Horder's Oration it is that the clinician, while not disdaining to utilize every advantage which bacteriology, biochemistry, pathology, and radiology place at his disposal for the investigation of disease, should show discretion in the adoption of new methods of treatment. But he should keep himself fully informed of all advances made in this field, and not hesitate to use new methods if they are superior or if the old ones are of no avail ; provided that the rationale is based upon scientific foundations, that after careful consideration they appeal to the intelligence, and that they appear to offer hope to the patient.

There is no need to worry about the " mass man " and the " direct actionist." If there is any good in their methods it will compel recognition. As in politics, " left wingers " are not all bad, nor are all " right wingers " good. Many methods in daily use to-day were the revolutionary measures—the " new treatments "—of our fathers. Was it not the father of the late Sir William MacCormac who was driven from his practice because he employed the open-air treatment for phthisis? The " new treatment " of yesterday has become the routine of to-day. Advances in knowledge of disease frequently make new treatments imperative. Diphtheria is no longer regarded as a local inflammation of the throat and treated with carbolic sprays, etc., nor is kala-azar now looked upon as a particularly deadly form of malaria which must *ipso facto* be treated with quinine. As Lord Horder remarks, " the pendulum of practice still swings." Of course it does, and it always will ; but when we bleed in the twentieth century we like to think that we do so with a sounder understanding of its indications and limitations. I once saw a patient with pneumonia who was moribund with a failing toxic heart and a blood pressure of 90/50. The doctor in attendance had made a " dog's dinner " of both ante-cubital spaces in an attempt to bleed him, because it said in the textbooks that bleeding would relieve an overloaded right heart. One cannot legislate for ignorance. The march of progress must continue, as it always has done ; all that is bad being forgotten because it is bad, and all that is good proving itself good. The specific of to-day may become contraindicated by to-morrow's discoveries. The seeing eye and the thinking mind are trusty safeguards against error and disaster.—I am, etc.,

H. M. STANLEY TURNER,
Wing Commander R.A.F. (ret.).

Abingdon, Berks, June 27th.

SIR,—Dr. W. N. Leak's statement (June 24th, p. 1127) that his baby " had a temperature of 104° and well-marked bronchopneumonia," that " she was at once given an ampoule of omnadin and the more usual treatment for her condition," and that " next morning her temperature was normal and remained so," needs emphatic challenging. I congratulate him on his daughter's miraculous recovery, and compliment his fatherly enthusiasm. But how can bronchopneumonia be well marked overnight? What proof is there that there was actually a pneumonia present, and not something simulating this? If we cannot prevent or abort a mere cold, how can we claim to nip pneumonia in the bud, especially when " well marked "? It is an ever-recurring experience for children to recover spontaneously from feverish chills.

One of the most urgent needs of the day is a power to curb the activities of drug manufacturers, with their new, expensive concoctions, labelled with insane names. Steps should also be taken to hand over, like unlicensed firearms, useless drugs in the *B.P.* What earthly use is lead, for example? It is a weight on therapeutics. Many dangerous drugs have some legitimate virtue and are eliminated by the body, but lead, externally and internally, is a poison, always valueless, which accumulates in the system. Leave lead to the plumbers.—I am, etc ,

J. KELVIN, M.B.

Glasgow, June 29th.

Use of Quinine in Normal Labour

SIR,—In your issue of April 1st (p. 587) Dr. W. A. Rees reports a case of retained placenta following the use of quinine to induce labour, and he asks if any readers have come across a similar experience.

In January, 1932, the wife of my Chinese house-surgeon, a primipara aged 21, was one week over time, and the measurements were small (interspinous 9 inches, intercristal 10 inches), so I suggested quinine. She was given quinine sulphate, 10 grains three times a day, for one day, after which labour commenced. The first and second stages were normal, and a nine-pound baby was delivered naturally. The placenta, however, would not come away, and, finally, after two hours, I removed it manually from the uterus—a very difficult task. At the

time we put it down to adherent placenta, the latter being of a very fibrous type, but it is conceivable that the 30 grains of quinine given may have had something to do with it.—I am, etc.,

Mackenzie Memorial Hospital, Tientsin, June 3rd. GEORGE C. DORLING.

"Total" Hysterectomy

SIR,—I was interested to read in the *Journal* of April 29th (p. 741) Dr. Ralph Worrall's paper on total hysterectomy for non-malignant conditions. I find it very difficult, however, to appreciate how he can possibly label the technique he describes "total hysterectomy." It is well known that the cervical glands and their cystic dilatations penetrate very deeply, and I feel sure that if Dr. Worrall were to excise what remains of the cervix after his "total hysterectomy," he would have no difficulty in satisfying himself that the operation he describes does not deserve the title he gives it.—I am, etc.,

Royal Hospital, Baghdad, June 11th. G. S. WOODMAN, F.R.C.S.Ed.

Paying Patients in Voluntary Hospitals

SIR,—Since you referred in the *Journal* of August 18th, 1928 (p. 317), to the report of the Pay Beds Committee of the King Edward's Fund for London, circumstances have brought all concerned very much up against the problems involved in this proposal. You then remarked that "changes in conditions in the metropolis will certainly have their reactions upon the country generally," and you went on to state that if the proposals made in that report are to be carried into effect "the ranks of the younger consultants will be steadily thinned." It is not only the interests of this group in the profession which will be affected, but also those of the visiting medical staffs and of the general medical practitioners.

At the Annual Representative Meeting of the British Medical Association to be held in Dublin this month this question will come up again for discussion, as on the agenda there appear proposals outlining the terms and conditions under which private patients should be received in voluntary hospitals; and therefore it is to be hoped that by free discussion and clear thinking it may be possible for the medical profession to put concisely before the public proposals which will be equitable to all concerned.

The proposals outlined in the Pay Beds Committee's report, that:

(*a*) accommodation provided in voluntary hospitals should be placed at the disposal of those of "moderate means" on the same terms and conditions as apply to the "sick poor"; no payment for medical treatment being allowed;
(*b*) the general practitioners should be "kept in contact with" these patients by communication, information, and advice;
(*c*) that the committee of management should lay down certain rules or limitations as to the medical practitioners who should be allowed to attend these patients;

are such as evidently appeal to the committees of management of many voluntary hospitals. Judging by the various schemes which are being launched by these committees, it would seem that they consider

(*a*) that private patients should be a source of income to the hospitals;
(*b*) that the visiting medical staff should be expected to contract to give their services for little or nothing;
(*c*) that the general medical practitioner, and the private young consultants, should be entirely detached from any association with the private patient department of these hospitals; and
(*d*) that the consultants and specialists of the visiting medical staffs, by attendance on all these private patients for whatever may be the illness, should become to all intents general medical practitioners.

The question of providing general medical practitioners with accommodation in the private patient department for those of their patients who require only "general medical practitioner" treatment does not seem to have been considered by the boards of management, or, if it has been, then it has been turned down as either impracticable or unnecessary. It is to be hoped, therefore, that the Representative Body will in definite terms announce, on behalf of the medical profession,

(1) that in all districts there should be available accommodation in voluntary hospital, nursing home, or/and otherwise, for private patients requiring "specialist treatment," and for those requiring "general medical practitioner treatment";
(2) that if a voluntary hospital enters into the business of providing accommodation for private patients then the administration of this department should be as far as possible on the lines recognized by the medical profession as those of a private nursing home;
(3) that the manner in which the public department of a voluntary hospital is conducted should not determine the manner in which the private patient department should be conducted;
(4) that there should be for the private patient: (i) free choice of doctor; (ii) admission on the recommendation of a private doctor; and (*a*) that the private medical practitioner, whether young consultant (not attached to the visiting medical staff) or the general medical practitioner, should have the entrée to the department as a right, along with the members of the visiting medical staff, and not as a matter of courtesy; (*b*) that the fees should be a matter of arrangement with the attendant doctor, gratuitous attendance neither being expected nor given.

If the medical profession does not unite on the above principles and secure their adoption then it will not be long before the general medical practitioner finds that if his patients go into the private patient department of a voluntary hospital he will lose them, or, alternatively, that he will be obliged to use a less well-equipped nursing home.

To endeavour to dissuade the medical profession from affirming now, and in clear terms, the desired position alongside the visiting medical staff for the younger consultants and the general medical practitioner, because in the opinion of some at this moment it will not be universally obtainable, will eventuate in a condition of affairs when it will have become too late. And once more medicine will have received a set-back; the "back-bone of the profession" will have been deprived still further of the experience and remuneration to which it is entitled; and the middle-class public will lose the advantage of that efficient medical attendance which is at its disposal and to which it is entitled.—I am, etc.,

Hove, July 1st. E. ROWLAND FOTHERGILL.

The G.P.'s Proper Work

SIR,—I think the note in your issue of June 24th, headed "Fee-splitting and the Law" (from a legal correspondent), one of the finest and most explicit articles I have ever read, and very much wanted by the general practitioner, who is degenerating and looking round for some means of making a living because of the incessant inroads into his practice caused by the eternal clinics and whole-time men and women who are robbing him of his ordinary practice. Take maternity practice alone. We are surrounded by district nurses, who attend the women wholesale in their confinements; half of them do nothing but sit and watch, and long after the women should have been relieved they call on the general practitioner to come and clear up the mess. I consider every primipara ought to have a doctor in attendance during her pregnancy and at the confinement. All these clinics and nurses are kept up by robbing the general practitioner of his lawful work. The two letters on "The G.P. and Midwifery," by Dr. Terence Robinson and Dr. Kathleen Vaughan, are very much to the point.—I am, etc.,

Wallington, June 26th. A. Z. C. CRESSY.

Obituary

J. A. MITCHELL, M.B., D.P.H.

Late Secretary for Public Health and Chief Health Officer, Union of South Africa

Dr. J. A. Mitchell, formerly Secretary for Public Health and Chief Health Officer of the Union of South Africa, died at his home in Rondebosch on June 12th, after a week of critical illness. Warned some years ago of his dangerously high blood pressure by cardiologists, both in Capetown and in Johannesburg, he nevertheless continued working at the very high pitch to which he was accustomed. He had enjoyed the most robust health. His high blood pressure was discovered by accident as the result of an *x*-ray examination of the foot because of some slight tendon trouble. The plate showed a calcified blood vessel. The sphygmomanometer, then applied for the first time in Dr. Mitchell's life, revealed the startlingly high pressure. In spite of some precautionary measures it remained consistently above 240 mm. for some ten years, until after his breakdown in 1930. This took place at Bangkok, where he was representing the Union Government at a meeting of the Leprosy Commission of the League of Nations Health Organization. During a very lengthy motor trip he experienced a unilateral numbness, but was unaware of its real significance until the journey's end, when the paresis was discovered on trying to lea[ve] the car. He returned immediately to South Africa instead of going to the further Leprosy Congress convened by the Leonard Wood Memorial Organization in Manila. He made a partial recovery and resumed duty for a short time, but owing to continued ill-health he found it necessary to relinquish his office permanently in April, 1932.

James Alexander Mitchell was born in Ireland in 1876, and was educated at Foyle College, Londonderry, and at Glasgow, Edinburgh, and Cambridge Universities. He was a civil surgeon in the Edinburgh military district for a year. He went to South Africa in 1899 as bacteriologist for leprosy research, Robben Island, for which post he was selected by Lord Lister, acting on behalf of the Cape Government. His great administrative ability, however, became evident almost immediately to Dr. Gregory, who was then in charge of the Health Service of the old Cape Colony, and within two years Dr. Mitchell was appointed assistant medical officer of health for the colony. This post he held until the time of union (1910), when he became assistant medical officer of health for the Union of South Africa. He occupied this post until 1918, when he was appointed Chief Health Officer. Two years later, when the new Department of Public Health was created—following on the terrible shock sustained by the country as the result of the influenza epidemic—he was made Secretary of that Department. This post he held until his retirement.

In addition to the dual appointment as head of the Department and Chief Health Officer, he was deputy chairman of the Union Council of Public Health, chairman of the Union Leprosy Advisory Committee, and a member of the South African Medical Council. He saw service in the great war, holding the rank of lieutenant-colonel with the South African Medical Corps. During the South-West Africa campaign he was assistant director of medical services for the Southern Force and lines of communication, and was mentioned in dispatches.

Dr. Mitchell represented the Union of South Africa on many Commissions. He was mainly instrumental in placing the present satisfactory health and medical registration legislation on the Statute Book; the medical profession is particularly indebted to him for his work in this connexion.

W. W. GREER, M.C., M.D., F.R.C.S.ED.

Dr. William Wells Greer died at his residence at Bedfont, Middlesex, on July 1st. He was born in Chester in 1876, but left England with his parents at an early age to begin his general education in Queensland, where he obtained a scholarship at Townsville Grammar School, afterwards going to the grammar school in Brisbane. He returned to Edinburgh in 1899 to study medicine at the Royal Infirmary, and graduated M.B., Ch.B. in 1904, receiving the doctorate in 1906 with special commendation for his thesis. He was a member of the British Medical Association. Dr Bramwell (afterwards Sir Byrom Bramwell) invited him to become his house-physician, which post he ultimately held for a year, but not until he had first served for six months as an assistant in general practice to a Dr. Carruthers in Congleton, Cheshire. The interruption of his hospital career at this stage was a great disappointment to him, but was rendered imperative by financial considerations. It was with characteristic determination that he took up the hard apprenticeship of an assistant in order to save the means which enabled him later to accept a second invitation from his old teacher, whose clinical example and personal influence undoubtedly moulded to a large extent Greer's own practical trend of thought. After finishing his time at the Royal Infirmary he returned to Australia to practise, and settled in Kyogle, Richmond River, N.S.W., where he built and organized his own hospital and established a well-deserved reputation as a surgeon. In 1913 he returned to Edinburgh to work for the F.R.C.S., which he obtained just before the outbreak of the war. In August, 1914, he joined the 1/3 Lowland Field Ambulance, with which he served throughout the war in Gallipoli, Palestine, France, and Belgium, being twice mentioned in dispatches and awarded the Military Cross. After the war he went to practise in Australia for five years. In 1925, while on holiday in Europe, he met with a serious accident, and sustained a fracture of the skull. This was the beginning of a long series of illnesses which led to his untimely death, though for the last five or six years he was able to carry on a successful practice at Bedfont.

A colleague writes: The combination of a rare imagination with an intensely practical attitude towards life gave to Greer an intellectual outlook which would have made him an ideal teacher of surgery had he remained in the academic world. Destiny, however, had marked him for the highways and byways of practice in a country in which distances were great and where many bricks had to be made without straw. Although precluded by the circumstances of his work from the opportunities for much reading or discussion of medical problems, he never lost the fine clinical instinct which, inherent from the beginning, had developed so strongly during his association with Bramwell. His knowledge of men was deep, his sympathy immense. The affection which he felt for his patients was blended with his intellectual gifts and his practical determination, and this gave his clinical work the character which it invariably showed, and which made his reputation among colleagues and patients one of which any man might well have been proud. Of this, however, Greer was largely unconscious, and the gentle and naïve surprise that he would exhibit at any outside praise was as beautiful as it was unaffected. Truly he was a doctor of the old school, whose life and work, like those of so many whose names are not writ large in the chronicles of men, will nevertheless remain an abiding example to the multitude of those who benefited by him, and still more to the smaller band of intimates to whom, by his strength and sweetness, he was so greatly endeared.

J. FORD ANDERSON, M.D.

Dr. J. Ford Anderson, who died on June 29th at his home in London in his ninety-fourth year, was at one time active in the affairs of the British Medical Association, which he joined as long ago as 1865. It is interesting to recall that another veteran member, Sir James Crichton-Browne, ten months his junior, was elected in 1866.

John Ford Anderson, son of the Rev. A. Anderson, LL.D., was born at Boyndie, in Scotland, on January 23rd, 1840, and was a kinsman of the late Sir Hugh Anderson, M.D., F.R.S., Master of Gonville and Caius College, Cambridge. He was educated at the Universities of Aberdeen, Edinburgh, and Paris, and obtained the L.R.C.S.Ed. in 1861, graduating M.D. and C.M.Aberd. in 1863. Many years later, at the advanced aged of 86, he became a member of the Royal College of Physicians of London. Before commencing practice in London he was for a time resident physician at the Middlesex Hospital, and from 1875 to 1893 lectured in obstetrics at the London School of Medicine for Women. In 1904, when chairman of the Hampstead Division, he was elected to the Council of the British Medical Association and to the Hospitals Committee, and served again on the Council in 1909–10, while president of the Metropolitan Counties Branch. In 1921, when the Association met in Newcastle, he was a member of the Representative Body. During two years of the war he had charge of St. Marylebone workhouse infirmary.

Dr. Ford Anderson was the author of one or two short clinical papers, and of articles on provident dispensaries and on ethical aspects of the hospital question. His presidential address to the Metropolitan Counties Branch, on home and hospital treatment of the poor and the low wage-earners, appeared in the *Supplement* to our issue of June 26th, 1909. In this he dealt more particularly with recommendations in the majority report of the Royal Commission on the Poor Laws, with special reference to London conditions. He was a member of the Royal Medico-Psychological Association, and had served on the council of the Federation of Medical and Allied Services. The conduct of a large practice in Hampstead, for much more than half a century, by no means exhausted his energy and zest for life. Among other interests in later years he was highly appreciative of the radio, and in 1932 gave a number of broadcast talks which brought him friendly letters from hundreds of listeners.

THE LATE MR. HAMILTON RUSSELL

Sir STCLAIR THOMSON writes:

The obituary notice of my fellow student, Hamilton Russell, in the *Journal* of June 24th is so sympathetic and complete that there is little one can add to it. For the sake of historical accuracy it would be well to correct a mistake which appeared in the *Times* and several other journals, saying that he "was the last of the house-surgeons to work under Lister." Now Hamilton Russell was a dresser in King's College Hospital with me when W. J, Penny of Bristol—a well-known quarter-miler and footballer—was house-surgeon. In 1881 Russell was clerk when the house-surgeon was Colonel R. Pratt Bond, R.A.M.C.; and he was himself house-surgeon in the session 1883–4, the year in which Lister received his baronetcy. Many years afterwards Hamilton Russell wrote of this as follows:

"I have a very vivid memory of an incident that occurred one afternoon when I was house-surgeon. I was walking with my illustrious chief up the great staircase of King's College Hospital to the wards, when he handed me a letter he had just received. It was a letter couched in language of incomparable grace, conveying to Mr. Lister the desire of Queen Victoria that he would accept a baronetcy in recognition of his service to the cause of suffering humanity. . . . And Lister was frankly and unaffectedly delighted; there was even something a little boyish in his pleasure, which for a moment struck me with vague surprise. Needless to say, however, the real source of his satisfaction was quite devoid of any sense of personal aggrandisement; he regarded the honour as a kind of sign manifest to all the world of the rightness of the surgical principles that he had laid down, and striven for, and taught. As he put it in an amusingly homely parlance, 'I dare say it will help things along.' What he was pleased to call 'things' comprehended all that we nowadays express in the term 'modern surgery.'"[1]

But Lister did not retire from hospital work when he became a baronet in 1883. He did not terminate his active work in King's until the year 1893.

At the annual meeting of the College of Surgeons of Australasia, in March, 1930, the Fellows presented Hamilton Russell with his portrait. In making the presentation Sir Henry Newland, the president, said: "As becomes a disciple in person of Lister, the great master and maker of modern surgery, Hamilton Russell is known to be humble-minded and modest; to have wisdom and foresight; to be honest in his desire to find truth; and to be stainless in word and deed." In acknowledging the presentation of an excellent oil portrait, the recipient spoke warmly of his good fortune in having been "a student in the hands of the greatest scientific surgeon the world has known." And he added: "He was something more than a great surgeon; he was a great idealist, who set no bounds to the loftiness of his ideals. From him I learned other things than the mere science of surgery. He told me that the profession I had chosen was the most exalted of all callings . . . and that the operating theatre of the hospital was a place more sacred than a cathedral. . . . With the memory of such a master ever present with me, I could not possibly stand here and accept this splendid gift at your hands without in spirit laying it at his feet."

Like all who came in direct contact with him, Hamilton Russell was inspired by Lister with a love of learning, a patience and constancy in the pursuit of truth, a sincerity of thought and word, and a lofty idealism. Like his great master, he was devoted to children, and was a life-long friend to his pupils and all his junior colleagues. He very aptly, in one of his addresses, quoted some lines of William Watson as applying to his own old chief. All who have in any way been connected with Hamilton Russell will agree that they also well describe the feelings of those who were privileged to be his fellow students, his pupils, his colleagues, his friends, or his patients:

> "'Tis human fortune's happiest height to be
> A spirit melodious, lucid, poised and whole;
> Second in order of felicity
> I hold it to have walked with such a soul."

THE LATE SIR WALTER FLETCHER

Dr. TH. MADSEN, president of the League of Nations Health Committee, writes from the State Serum Institute, Copenhagen:

Among the many who have felt the much too early death of Sir Walter Fletcher as a very painful loss must also be counted the Health Organization of the League of Nations. In a variety of ways Sir Walter Fletcher gave us advice and assistance of important consequence, and I would particularly emphasize the interest which from the very first he took in the work that is being done by the Permanent Commission on Biological Standardization. As you will be aware, some of its most important activities are concentrated in the National Institute for Medical Research at Hampstead, under the leadership of Sir Henry Dale and his highly efficient staff, and these activities have always had the advantage of Sir Walter Fletcher's active and able support. For these reasons the Health Organization feels deeply indebted to him, and will always cherish his memory.

THE LATE MR FRANK JEANS

The first part of the funeral service for the late Mr Frank Jeans was held in Liverpool Cathedral on June 23rd, in the presence of a large congregation, including many representative members of the University, the Royal Infirmary, the Medical Institution, and the medical profession generally We print below extracts from personal appreciations written by leading colleagues in Liverpool

Professor R E KELLY writes Always a surgeon of broad interests, his chief work centred in urology, a specialty in which he so excelled that he was elected president of the Urological Section of the Royal Society of Medicine, an honour of which he was very proud In many ways Jeans was a true pupil of Banks Each in his turn was the best after dinner speaker in our city Jeans had a fund of humour of a whimsical flavour all his own, while his rapier like wit and felicitous turn of phrase were a constant delight He was very much loved, and will be greatly mourned A generation of medical students will remember what he said when much of their medical teaching has faded into the twilight of forgotten things

Professor JOHN HAY writes We knew him as a man of great courage, in whom there was nothing mean or paltry, outspoken, fearless, and with a soul full of kindliness His was a fine, big, generous nature, permeated with that rare quality, the gift of charity When he spoke it was as a master of happy speech and felicitous phrases, and his friends and students will always remember with pleasure and profit the witty aphorisms with which he enlivened his conversation But behind the wit and the humour was sound judgement, based on wide knowledge and an uncanny understanding of human nature, and to him to understand was to forgive

---

We regret to announce the death, on June 24th, at Clapham Park, S W , of Dr J GRAY DUNCANSON, at the age of 62 He was the younger son of the late Rev P C Duncanson, and was educated at Hamilton, Glasgow Academy, and Glasgow University, where he passed his final examination for the M B and C M with commendation at the age of 20, graduating when 21 He acted as assistant to Dr Gowans of South Shields, and on returning to Glasgow was appointed resident medical officer in the Victoria Infirmary He then paid an extensive visit to the East, and in 1894 carried on a large general practice in the Woolwich, Shooters Hill, and Blackheath district with his elder brother, Dr J C Duncanson In 1914 he joined the R A M C , and organized the Auxiliary Hospital, Woolwich, later commanding the medical division at the Royal Herbert Hospital Proceeding to France he became registrar, and organized in great measure No 72 General Hospital, Deauville He rose rapidly to the rank of major, and was twice mentioned in dispatches From 1920 he held the appointment of regional medical officer at the Ministry of Health, which work he was carrying on at his death Dr Duncanson had been secretary and vice president of the Therapeutical Section of the Royal Society of Medicine, and for some years he was a member of the National Formulary Subcommittee of the Insurance Acts Committee

---

The following well known foreign medical men have recently died Geh Med Rat Professor RODERICK STINTZING, formerly director of the Medical Clinic at Jena, aged 80 , Professor C E OVERTON, emeritus professor of pharmacology at Lund, aged 68 , Dr ROBERT SCHELLER, *extraordinary professor of Hygiene at Dresden*, aged 57 , Lieutenant General PAUL DEMOLDER, inspector of the health service of the Belgian Army and Commander of the Order of St Michael and St George, and Commander of the Legion of Honour ; Dr F G GADE, formerly editor of *Norsk Magasin for Laegevidenskaben*, aged 73 , Dr EDOUARD JULIAN, co editor of *L'Interprète des Chercheurs et Curieux*, aged 59 , Dr V HUTINEL, formerly professor of children's diseases in the Paris Faculty of medicine and Commander of the Legion of Honour , and Dr R SOUTTER, a Boston orthopaedic surgeon

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

OPENING OF NEW BUILDINGS

The new buildings of the Medical School of King's College Hospital, Denmark Hill, were opened on July 4th by H R H Prince George Admiral of the Fleet Earl Beatty, the new chairman of the hospital committee of management, presided over the ceremony, which was attended by the Vice Chancellor of the University of London, the Mayors of Camberwell and Lambeth, and the members of the school and hospital staffs Lord Beatty reminded the gathering that King's College came into being in 1829, the Medical Faculty in 1830, and King's College Hospital in 1839 Until the hospital was founded the medical students had had to walk the wards of other hospitals The hospital was in proximity to the College in the Strand until 1913, when it was removed to Denmark Hill A few years ago it was decided to celebrate the centenary of the Medical School by taking in hand a much needed extension, and the new buildings resulting from that project he asked the Prince to open

Prince George said that medicine and surgery, with all their specialized branches, were progressing steadily year by year, and to keep pace with this progress the task of the teacher and the student alike grew ever more exacting It was therefore essential that the student should take full advantage of the modern methods of medical education But the school had another function in addition to the training of students—namely, the study of disease and research into its causes, with the object of advancing its treatment and prevention To celebrate the centenary of the school the authorities had wisely decided to extend its facilities for the exercise of both these functions He added that the records of the school during the past one hundred years contained the names of many distinguished physicians and surgeons, but two of them deserved special mention—namely, Lister, the association of whom with King's College Hospital and School for sixteen years would ever make it famous, and David Ferrier, who, in its neuro pathological laboratories, carried out his great researches into the functions of the brain

The Dean (Dr J A Drake) then gave a brief account of the new buildings The decision to extend the Medical School, he said, was not prompted only with the object of celebrating the centenary , additional accommodation had become essential owing to the increased number of students In planning the new buildings both the education of the student and the necessities of research had been kept in mind, and provision had been made for further extension should this be desirable in the future First and foremost, there was a large pathological museum of modern design , additional class rooms had been provided , a large laboratory had been built and equipped for biochemistry, and a number of smaller laboratories would be at the disposal of the medical and surgical staff, and also of younger men who were qualified to use them and anxious to investigate any special problem of disease In addition there were large common rooms for men and for women students, and a refectory hall, which could also be used for special lectures and meetings and for such events as the annual opening ceremony of the winter session The cost of the new buildings was approximately £40,000, towards which £10,000 had been voted by the Court of the University of London Other sums had been collected from well wishers by the Dean Emeritus (Dr Willoughby Lyle), and the building fund had also been greatly increased by the policy of financial conservatism which had been pursued by the school for some years past, but a building debt of approximately £5,000 remained

An inspection of the school was then made by the general company The teaching museum while allowing a complete general view, is arranged in separate bays for classification purposes and for the instruction of students in the various branches of medicine, surgery and obstetrics The biochemical research laboratory has been constructed on an additional floor over the original

students' pathological laboratory, and the work in it will be run in conjunction with the reconstructed diabetic clinic of the hospital. There is also a dental museum, which will provide all the accommodation necessary for the increasing number of specimens which are being collected by a growing dental school.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

THIRD M.B.—(*Part I, Surgery, Midwifery, and Gynaecology*): S. T. Anning, T. M. Bell, N. B. Betts, W. R. Billington, G. O. A. Briggs, J. C. Buckley, F. Clifton, E. L. Cohen, W. J. B. de Gruchy, J. H. Dixon, A. B. Evans, S. M. Evans, G. L. Foss, W. R. Gavin, W. E. F. Gough, E. M. Griffin, E. R. Hargreaves, N. H. Harwood-Yarred, J. D. Hay, E. C. Herten-Greaven, G. T. Hindley, A. C. L. Houlton, W. R. S. Hutchinson, L. G. Irvine, G. H. Jennings, A. Kekwick, J. H. Lankester, J. C. Lee, R. S. Lewis, W. H. Lewis, M. K. Martyn, F. S. A. Maw, W. B. Mumford, W. F. Nicholson, G. S. W. Organe, E. W. Price, E. G. Pyne, L. R. J. Rinkel, G. C. D. Roberts, H. J. M. Robinson, M. A. Rugg-Gunn, J. H. Shakespeare, J. Smart, J. T. W. Spiridion-Kliszczewski, S. M. Thompson, O. A. Trowell, J. G. Vincent Smith, E. O. Walker, G. E. Walker, H. C. M. Walton, W. F. Walton, G. L. Ward, V. H. Wilson. *Women*: P. L. Holliday, F. C. Naish, M. C. A. Robson, R. A. Rushton, E. D. Thompson. (*Part II, Principles and Practice of Physic, Pathology, and Pharmacology*): G. L. Alcock, S. T. Anning, W. T. C. Barber, H. Barcroft, G. F. Barran, C. G. Batty-Smith, W. T. C. Berry, E. J. M. Bowlby, G. O. A. Briggs, K. L. Buxton, R. Cairns, C. M. Carr, A. H. Charles, E. L. Cohen, A. G. Cross, W. Dykes Bower, G. L. Foss, P. H. R. Ghey, J. N. Groves, M. I. A. Hunter, W. R. S. Hutchinson, L. G. Irvine, J. G. Jones, D. Kyle, A. W. Langford, A. B. MacGregor, W. S. McKenzie, T. C. Maling, J. W. Maycock, A. Miller, M. P. Morel, J. G. More Nisbett, H. J. V. Morton, B. C. Murless, R. Q. Parkes, E. W. Price, J. S. M. Pringle, S. A. Propert, I. G. Robin, G. Scott, E. Sharp, E. P. Sharpey-Schafer, D. W. Smithers, J. G. C. Spencer, R. A. Sykes, E. W. Taylor, G. W. Thomas, H. B. Tipler, O. A. Trowell, T. M. Tyrrell, G. I. Watson, R. H. H. Williams, J. Wilson. *Women*: D. K. Emery, M. Sutcliffe.

UNIVERSITY OF BIRMINGHAM

At a congregation held on July 1st the following medical degrees were conferred:

M.D.—F. H. Healey.
M.CH.—W. Gemmill, B. Lloyd.
M.B., CH.B.—*D. M. Brown, *†C. S. Whitehouse, H. C. Aston, G. R. Clarke, A. C. Edwards, R. E. P. Field, J. G. H. Frew, A. Hemming, ‡J. Montgomerie, Emma D. N. Part, F. J. Rutter, W. P. Stevens, J. L. Whatley.

* Second-class honours. † Distinction in surgery.
‡ Distinction in medicine.

The following scholarships and prizes have been awarded: *Queen's Scholarships*: (Third year) L. W. Aldridge, (fourth year) H. B. Hunt, (fifth year) J. S. Mitchell, (final year) C. S. Whitehouse. *Arthur Foxwell Memorial Medal*: (Final year) J. Montgomerie. *Sampson Gamgee Memorial Medal for Surgery* (final year) and *Priestley Smith Prize for Ophthalmology* (final year): C. S. Whitehouse. *Russell Memorial Prize*: O. A. Trowell. *Peter Thompson Prize in Anatomy*: (Third year) E. J. Goldman.

UNIVERSITY OF DURHAM

At the Convocation held on June 27th, presided over by the Chancellor, Lord Londonderry, the honorary degree of D.C.L. was conferred on Lord Horder, M.D., F.R.C.P., physician-in-ordinary to the Prince of Wales and senior physician to St. Bartholomew's Hospital.

UNIVERSITY OF SHEFFIELD

Constance N. Jenkinson has been approved for the degree of M.D.

UNIVERSITY OF GLASGOW

At a meeting of the Senate on June 30th Professor D. F. Fraser-Harris, M.D., D.Sc., was awarded the triennial prize (for 1932–3) in the history of medicine for an essay on "Antiseptics before Lister."

UNIVERSITY OF WALES

The following candidates have satisfied the examiners in the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—(*Part I*): G. J. Roberts, Jean J. Smith, Anne E. Williams-James.

NATIONAL UNIVERSITY OF IRELAND

HONORARY DEGREES

The Senate at its recent meeting decided that honorary degrees, as follows, should be conferred in connexion with the forthcoming Annual Meeting in Dublin of the British Medical Association:

LL.D.

Professor T. Gillman Moorhead, M.D., P.R.C.P.I., as President of the Royal Academy of Medicine in Ireland, and in recognition of his eminence in his profession.

Sir Humphry Rolleston, Bt., G.C.V.O., M.D., D.Sc., LL.D., in recognition of his services as late Regius Professor of Physic at Cambridge University, and of his association with the National University of Ireland as an extern examiner.

M.D.

Sir Robert Bolam, LL.D., M.D., F.R.C.P., in recognition of his work as former Chairman of Council of the British Medical Association.

Sir Henry Brackenbury, LL.D., M.R.C.S., as Chairman of Council of the British Medical Association.

D.Litt.

T. Percy C. Kirkpatrick, M.D., F.R.C.P.I., in recognition of his contributions to literature.

D.Sc.

Professor Joseph Barcroft, F.R.S., in recognition of his eminence as a physiologist, and of his long association with the University as an extern examiner.

Rufus Cole, M.D., Director of the Rockefeller Medical Research Hospital, New York City, in recognition of his eminence in medical research.

Professor Dean Lewis, M.D., in recognition of his work as President of the American Medical Association.

Professor Thomas H. Milroy, M.D., B.Sc., LL.D., Professor of Physiology in Queen's University, Belfast, and for many years extern examiner in the National University of Ireland.

Sir Edward Sharpey-Schafer, LL.D., Sc.D., F.R.S., in recognition of his contributions to scientific literature.

D.Sc. (*Public Health*)

Professor J. M. Beattie, M.D., in recognition of his services to public health, and of his association with the University as an extern examiner.

Sir Leslie Mackenzie, LL.D., M.D., F.R.C.P.Ed., in recognition of his services to public health.

Sir John William Moore, M.D., F.R.C.P.I., D.P.H., in recognition of his services to public health, and as Past-President of the Royal College of Physicians of Ireland.

M.Ch.

John F. O'Malley, F.R.C.S., a distinguished former student of Queen's College, Galway, and in recognition of his eminence as an oto-rhinologist.

Sir Hugh Rigby, Bt., K.C.V.O., M.S., F.R.C.S., in recognition of his eminence as a surgeon.

UNIVERSITY COLLEGE, CORK

The following candidates have been approved at the examinations indicated:

M.B., B.CH., B.A.O.—J. J. Linehan (second-class honours), J. S. Kelleher, M. F. Kelleher, J. G. O'Sullivan. (*Part I*): C. J. Cantillon, P. J. Geoghegan, H. L. Lentin, J. P. O'Leary. (*Part II*): M. Flavin.

M.D.—J. D. Riordan, R. C. Webster.

D.P.H.—Mary C. O'Connell.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Primary Fellowship Examination

The following have been successful at the First Professional Examination for the Diploma of Fellow:

E. S. Allin, G. N. Bailey, M. Baillie, Alice J. M. T. Barnes, P. Baron, R. J. V. Battle, B. J. Bickford, A. N. Birkett, A. W. Bone, Arabinda Chaudhuri, J. A. Cholmeley, E. J. Collins, W. S. Diggle, D. B. Fraser, K. D. Fraser, O. M. Galal, S. Glaser, H. C. P. Gunewardene, T. S. Heslop, L. J. Honeywill, J. S. Horn, L. J. Horn, J. Hughes, D. W. Jolly, H. Josephs, Marjorie F. Landau, V. D. Logue, J. N. Madan, I. Magdi, I. W. Matheson, D. N. Matthews, B. W. Nairn, W. McN. Niblock, J. C. Nicholson, G. W. Palmer, M. M. Pandya, Dorothy J. Perkins, S. Rameshwer, E. P. Rigby, Elaine M. K. Salmond, D. M. Samuel, D. A. Sanford, J. Scholefield, A. K. Sen, B. K. Sheorey, J. F. Shepherd, M. Z. R. Siddiqui, D. Slome, T. M. Smith, R. R. S. Strang, S. Sunkavally, W. H. Sweet, H. G. Ungley, J. R. Vaid, D. Whitteridge, D. Wilkie, B. L. Williams, R. H. Young.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—J. L. Cope, S. A. de Souza, H. M. el Magidi, T. E. Mitchell, P. J. Purcell.

MEDICINE.—W. H. Ekin.

FORENSIC MEDICINE.—E. Cohen, S. Gurevich, S. G. Nathan, A. W. Turner.

MIDWIFERY.—E. C. Dax, T. Gardner, A. E. Glanvill, N. C. Lendon, R. M. Outfin.

The diploma of the Society has been granted to Messrs. W. H. Ekin, A. E. Glanvill, S. Gurevich, and T. E. Mitchell.

The Services

Lieut.-Colonel H. M. J. Perry, O.B.E., R.A.M.C., has been appointed Honorary Surgeon to the King, and is promoted brevet-colonel, vice Major-General H. Ensor, C.B., C.M.G., C.B.E., D.S.O., late Royal Army Medical Corps (ret.).

R.A.M.C. COMMISSIONS

Twenty-five permanent commissions in the Royal Army Medical Corps will be offered on July 27th, and applications should reach the War Office not later than July 21st. Candidates will be selected for commissions without competitive examination, and will be required to present themselves in London for interview and medical examination. They must be under 28 years of age on August 1st, 1933, and registered under the Medical Acts. All particulars may be obtained from the Assistant Director-General, Army Medical Services, the War Office, Whitehall, S.W.1.

DEATHS IN THE SERVICES

Major Robert George Thompson, R.A.M.C. (ret.), died on May 15th, aged 71. He was born at Cork on November 29th, 1861, and was educated at Queen's College, Cork, graduating M.D., M.Ch. in the Royal University of Ireland in 1883. Entering the R.A.M.C. as surgeon on May 30th, 1885, he reached the rank of major after twelve years' service, and retired on January 7th, 1903, but rejoined for service on the outbreak of the great war on August 6th, 1914. He served in Burma in 1885–7, receiving the frontier medal with a clasp; in Sierra Leone in 1898–9, in the Karene expedition (medal with clasp); and in the South African war, taking part in operations in Cape Colony in 1901.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Ministry of Health Vote was chosen for debate in the House of Commons this week. Discussion also arose on the Foreign Office Vote, the Board of Trade, the Forestry Commission, and the proposed special grant of £500,000 to distressed areas.

In the House of Lords on June 28th the Royal Assent was signified to the Finance Act, the Pharmacy and Poisons Act, and other measures. No day has yet been appointed for the Pharmacy and Poisons Act to come into force.

The Samaritan Free Hospital for Women Bill was read a first time in the House of Commons on June 28th.

On July 4th, in the House of Lords, the Manchester Royal Infirmary Bill was read a second time.

Superannuation of Mental Hospital Officers

On June 28th the House of Commons in committee considered the Local Government and Other Officers Superannuation (Temporary Provisions) Bill On Clause 1 ("Certain reduction in remuneration to be disregarded for purposes of superannuation") Mr. SHAKESPEARE, for the Ministry of Health, accepted an amendment, moved by Sir Henry Jackson, to add after the word "computing" the words "for purposes relating to superannuation." Further drafting amendments were made without discussion, and the committee agreed to substitute September 1st, 1931, for October 1st, 1931, as the start of the period to which the Bill applied. Sir Henry also proposed that the Bill should cover cases where reductions of salary were made for the first time after October, 1933. Mr. Shakespeare could not accept the amendment, because by April 1st, 1932, the various associations had been told by the Ministry that if any further arrangements regarding pensions were made they would be *ultra vires*. The amendment was negatived. Mr. GREENWOOD said he had an amendment to make it clear that officers or servants to whom the Asylum Officers Superannuation Act, 1909, applied should be in the Bill. There was doubt whether an understanding between the Mental Hospitals Association and those employed at mental hospitals was a bona fide understanding within the terms of the Bill. It might be that the Mental Hospitals Association had no authority to impose any understanding it might reach with the British Medical Association or the Mental Hospital Workers' Union. It now appeared in the opinion of the Ministry of Health that, as regards this section of the public service, an understanding was not an understanding. The Minister had refused to discuss this question with the organizations concerned. Mr. GREENWOOD thought it clear that there had been an understanding between the Mental Hospitals Association and bodies of officers and servants that, in consideration of voluntary reductions of salaries and wages, superannuation rights should be maintained. Mr. SHAKESPEARE replied that asylums officers would be treated exactly as anybody else. They would be included in the Bill if, in fact, an understanding was made in good faith between the visiting committees and their officers. If agreements had been reached between national bodies that would be evidence that there had been an understanding. Local agreements would be considered too.

Further, on Clause 1, Captain ELLISTON moved an amendment designed, as he explained, so that local authorities should have a chance to reconsider their position in respect of the Bill and to adjust the superannuation in the case of those persons whose pensions they wished to secure. He said that in September, 1931, on the publication of Memorandum No. 1122 of the Ministry of Health, the Association of Mental Hospital Workers consulted the British Medical Association and the Royal Medico-Psychological Association and other bodies interested, and submitted a scale of reductions, which was accepted by the visiting committees. In due course the Ministry of Health pointed out that, subject to the amendment of the Asylum Officers Superannuation Act, the pensions must be based on the actual salary paid. Of sixty-six hospitals outside London nine made no reductions and were unaffected by this Bill, twenty-four continued to make superannuation deductions based on the original scale, and twenty-seven acted on the advice of the Ministry. The Bill whitewashed or indemnified the hospitals which ignored the Ministry's advice, while the twenty-seven which acted in accord with it would be outside the terms of the Bill. If that were accepted, injustice would be done to a large number of local government officers. The final circular of the Ministry, issued three months ago, said that unequal treatment would give rise to discontent among the officials. Mr. SHAKESPEARE could not accept the amendment. He knew the interest Captain Elliston took in these cases. The amendment struck at the principle of the Bill. It would bring in cases that were not made with the understanding that a cut in remuneration should not affect pensions. The amendment was unacceptable because the principle was applied first to personal pension. The amendment was withdrawn. Mr. Shakespeare gave Mr. Greenwood an assurance that asylum officers, being appointed by the council or visiting committee, would be within the scope of the Bill.

The Bill then passed through committee, and was set down for report.

The later stages of the Local Government Superannuation Bill was set down for July 5th in the House of Commons.

Prison Governors and the Health of Prisoners

In moving a Vote for Police in England and Wales on June 30th, Sir JOHN GILMOUR said that traffic offences, mostly connected with motor cars, accounted for 43 per cent. of all criminal proceedings in 1931. There had been in recent years a decrease in such offences as drunkenness and sleeping out. Broadly speaking, there was improvement in social conditions and social behaviour. In crimes involving the taking of life there had been no increase over the past twenty years. Lady ASTOR said that sexual offences against young persons were increasing. Offenders—men who were not normal—were sent to prison, came out, and again committed these appalling offences. There should be some other way of treating such a man. If there was no other way but prison he ought to be kept there for life. She urged the Government to bring in a Bill incorporating the recommendations made by the Committee on Sexual Offences against

Young Persons, by the Committee on the Treatment of Juvenile Offenders, and by the Committee on Persistent Offenders.

The Vote for Police was technically withdrawn to allow a discussion on the Vote for Prisons in England and Wales. General SPEARS raised the case of an ex-soldier who was sentenced at Coltshill to fourteen days' imprisonment for sleeping out. The man went to prison quietly, but would not keep his cell door closed, and was agitated. He was brought before the acting governor and sentenced to three days' solitary confinement on bread and water. Subsequently at the inquest the prison doctor, Dr. Humphrey, said the man might have had some degree of claustrophobia, which would be aggravated by being alone and silent. That doctor gave a certificate that the prisoner was a fit man, and in a fit condition to undergo solitary confinement. The acting governor had punished the prisoner for being in a state of frenzy. During the journey to the punishment cell he took a leap forward down a flight of stone steps, and received an injury on the back of the head, behind the ear, which was not noticed. He was put into the punishment cell and died in a few minutes. This occurred in Winson Green Prison. Sir FRANCIS FREMANTLE said that governors of prisons had an immensely difficult task. Things would be carried too far if the description "claustrophobia" were applied to the objection of every prisoner to being shut in a cell. Medically speaking, the general meaning of claustrophobia was clear but indefinite. It was extremely difficult to be sure of that condition in another person. There was some claustrophobia, some feeling against being shut up, in the case of every prisoner. What was required was a close supervision of prisoners of nervous temperament during the whole of their time in prison, without waiting until they complained. There should be constant reports to the governor. The ordinary procedure was for the medical officer to keep under his supervision all the prisoners at all times. Could the governor say that he was in touch with the medical officer in regard to this case, and was alive to the medical aspect? Earl WINTERTON asked Sir Francis Fremantle to say if an injury of the kind which caused this man's death would not have been noticed by persons standing near when he fell. Sir Francis said there were many injuries, as in the hunting field, where little was apparent at the time, but where, if there had been fracture of the skull, a man might drop dead within half an hour. In the Army the commanding officer was responsible for the health of his troops, and had to take the advice of the medical officer. Was a governor of the prison responsible for the life of his prisoners and in constant touch with the medical officer? Was there any scheme for some kind of training of prison governors in the care of health and mentality? Combatant officers in the Army had to go through a regular course in this. He did not believe there was any such training for prison governors before or after appointment.

Mr. HACKING said there was no need for further inquiry into the case raised by General Spears. The prisoner had twice previously been arrested for sleeping out, but had been discharged. After he got to prison he was unruly and almost violent practically the whole time. The prison doctor said clearly that claustrophobia was not the cause of the man's death. Some of his actions might have indicated claustrophobia, but on balance the prison doctor reached that conclusion. He was glad Sir Francis Fremantle had made a statement on the number of prisoners who made out they suffered from this complaint. The governor of any prison was responsible for the health of the prisoners, but was always guided in matters of health by the prison doctor. He also gave due weight, as in this case, to the opinion of his medical officer as regards the psychology of the prisoners. It was after the man was dead that the prison officer at Winson Green agreed that claustrophobia was a possible explanation of the frenzy. The jury came to the conclusion that no blame attached to anyone, and he—Mr. Hacking—could not see that any further action was necessary or desirable. Answering Sir Francis Fremantle, he said knowledge of health condition, sanitation, and psychology was not demanded in the appointment of governors or deputy governors as a general rule, although some governors had special knowledge. Mr. Hacking mentioned that consideration was being given to the question of introducing legislation authorizing long sentences of detention for persistent offenders over 21.

Mr. RHYS DAVIES remarked that violence against the person and malicious and felonious wounding had gradually decreased since the war.

After discussion upon the treatment of young offenders the debate was adjourned.

University Degrees: A New Bill Introduced

In the House of Lords on June 29th Lord JESSEL secured permission to withdraw the Universities Spurious Degrees (Prohibition of Use and Issue) Bill. He said considerable objections had been taken to the Bill on account of its faulty drafting. He proposed, therefore, to introduce a new Bill, the University Degrees Bill, to make provision with respect to the unauthorized grant, issue, use, or assumption of university degrees, and with respect to the penalties to be imposed in respect of such unauthorized grant, issue, use, or assumption. The new Bill was then read a first time without debate, and ordered to be printed.

Disablement from Nystagmus.—On June 26th Sir J. GILMOUR, replying to Mr. Tom Smith, stated that the number of cases of nystagmus for which certifying surgeons in Great Britain gave certificates of disablement during the years 1920 to 1931 inclusive were: 1920, 2,216; 1921, 1,986; 1922, 4,047; 1932, 4,050; 1924, 3,446; 1925, 3,564; 1926, 1,863; 1927, 2,205; 1928, 2,515; 1929, 2,677; 1930, 3,248; 1931, 2,829. The tabulation of the figures relating to 1932 was not complete. In a certain number of the above cases the decision of the certifying surgeons had been reversed by the medical referee, but precise figures were not available.

Reports of Sitting Commissions.—On June 28th Mr. HORE-BELISHA furnished a list of committees and commissions still sitting. Among those which he expected to report in the course of the present year were the following: Workmen's Compensation (Industrial Diseases)—to inquire into the inclusion of turpentine poisoning and papilloma; Medical and Dental Branches of Defence Services—to investigate the cause of the shortage of officers and nurses; Mental Disorder and Sterilization of the Mentally Unfit—to consider the causation of mental disorder and the value of sterilization as a preventive measure.

Housing Progress in England and Wales.—Sir HILTON YOUNG told Mr. Price on June 29th that the number of houses completed in England and Wales during the years ended March 31st, 1932, and 1933, was:

	With State Assistance		Without State Assistance
	By Local Authorities	By Private Enterprise	
March 31st, 1932 ...	67,576	2,333	130,903
March 31st, 1933 ...	54,565	2,493	143,437

These figures referred to houses of a rateable value not exceeding £78 (£105 in the Metropolitan area).

The Boundary Limit of Ambulance Service.—Mr. DORAN asserted on June 29th that local arrangements all over the country did not permit an ambulance to render aid, even in the case of a serious accident, in an adjoining district. Sir HILTON YOUNG replied that he was unaware of this, but was causing inquiries to be made into the circumstances of a case recently reported, in which difficulty arose. He would consider whether any general action was necessary.

The Noise Nuisance.—During the twelve months ended May 31st, 1933, there were 2,930 prosecutions in the metropolitan police district for noise offences in connexion with motor vehicles.

Notes in Brief

In [illegible] colliery explosions in the United [illegible] the total deaths being sixty-[illegible]

[illegible] L. Cope, S. A. Mitchell, P. J. Purcell.

MEDICINE.—W. H. Ekin.

[illegible]SIC MEDICINE.—E. Cohen, S. Gu[illegible] report of the Chief [illegible] C. Dix, T. Gardner, A. E[illegible]onth.

London, R[illegible] Society has been granted [illegible] W. H. Ekin, A. E. Glan[illegible] S. Gurevich, and T. E. [illegible]

DIPLOMA IN PUBLIC HEALTH.—(*Part I*): G. J. Roberts, Jean J. Smith, Anne E. Williams-James.

Medical News

The new Freemasons' Hospital and Nursing Home at Ravenscourt Park, Hammersmith, of which a short account was given in the *Journal* of May 13th (p 840), will be formally opened on Wednesday, July 12th, by the King, who will be accompanied by the Queen

The fifteenth annual meeting of the Mental Hospitals Association will be held at the Guildhall, London, on Wednesday, July 12th, at 11 a m

The next series of lectures and demonstrations on tropical hygiene, intended for men and women outside the medical profession proceeding to the Tropics, will be given by Lieut Colonel G E F Stammers from July 10th to 19th The synopsis and other particulars can be obtained from the secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W C 1

The Fellowship of Medicine announces a demonstration of *x*-ray films (especially suitable for M R C P candidates) by Dr Peter Kerley, on July 13th, at 4 p m , at 11, Chandos Street, W In the absence of special courses attention is called to the individual clinics which are available daily by arrangement with the Fellowship The number of post-graduates attending each clinic is strictly limited, the usual maximum being four These clinics cover almost every branch of general medicine and surgery, and a full list is printed each month in the *Post Graduate Medical Journal*, or can be obtained on application to the Secretary, Fellowship of Medicine, 1, Wimpole Street, W 1

The quadrennial meeting of the International Council of Nurses will be held in Paris and Brussels from July 9th to 16th Mlle L Chaptal, president of the National Association of Trained Nurses of France, will preside, and some 5,000 trained nurses from all over the world are expected to attend The National Council of Nurses of Great Britain has nominated Miss Alicia Lloyd Still, C B E , R R C , for the position of president of the International Council of Nurses, and has also extended an invitation to the council to meet in London in 1937 The council is to receive official recognition from the French and Belgian Governments, and members of the congress will be received by the King and Queen of the Belgians

The third International Congress for Experimental Cytology will be held at Cambridge from August 21st to 26th Among the topics to which special attention will be devoted are cell respiration and metabolism , cell form and function as demonstrated by recent advances in tissue culture , the electrophysiology of the cell , the mechanism of development , and the cultivation of animal and plant viruses Those wishing to attend the congress are asked to communicate as soon as possible with Dr H B Fell, Strangeways Research Laboratory, via Cherryhinton, Cambridge, from whom further information may be obtained

The third congress of the Societas Oto rhino laryngologica Latina will be held in Paris from July 24th to 26th, with M Justin Godard, former Minister of Public Health, as president of honour, and Dr H Bourgeois as president A report will be made on nerve deafness The subscription is 100 French francs, which should be sent to Dr Chavanne, 5, Place des Cordeliers, Lyons

The Congress of French speaking Physicians will be held at Quebec on August 27th, under the presidency of Professor Rousseau, dean of the medical faculty of Laval

The six opening papers in this month's *Practitioner* are devoted to the newly born child, his care and management, and some of the diseases and defects to which he is liable

The issue of *La Medicina Ibera* for June 10th contains an illustrated account of the seventh international congress of military medicine and pharmacy recently held at Madrid, with portraits of the principal members

The issue of the *Gazette des Hôpitaux* for June 24th is devoted to tuberculosis

Sir Richard Gregory, Bt , Editor of *Nature*, has been elected a Fellow of the Royal Society under the provisions of Statute 12, which provides for the recommendation by the Council of "persons who, in their opinion, either have rendered conspicuous service to the cause of science, or are such that their election would be of signal benefit to the Society"

Applications are invited by the Association of Surgeons of Great Britain and Ireland for a surgical scholarship of the value of £350, to be held for one year The object of the scholarship is to enable the holder to pursue a definite line of research or to study surgery in specified clinics, either at home or abroad The election will be made in November, and applications must reach the secretary of the Association, 65, Portland Place, W , by September 30th

All appeals against the sentences in the Lübeck trial have been rejected by the German High Council of Appeal

Sir Henry Lunn Ltd is arranging to run passenger aeroplanes to Dublin during the Annual Meeting of the British Medical Association The return fare will be £13, which includes road transport between London and Heston aerodrome and also between Dublin aerodrome and the centre of the city Special services can also be arranged at reduced rates if return booking is guaranteed. Sir Henry Lunn Ltd also contemplates running a service by flying boat from Blackpool to Dublin An announcement appears in our advertisement pages this week, and further particulars will be published in the *Supplement*.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, B M A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1 on receipt of proofs Authors overseas should indicate on MSS if reprints are required, as proofs are not sent abroad

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBER** of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines)

The **TELEGRAPHIC ADDRESSES** are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) *Articulate Westcent, London*
MEDICAL SECRETARY, *Medisecra Westcent London*

The address of the Irish Office of the British Medical Association is 18 Kildare Street, Dublin (telegrams *Bacillus, Dublin*, telephone 62550 Dublin); and of the Scottish Office, 7, Drumsheugh Gardens Edinburgh (telegrams *Associate, Edinburgh*, telephone. 24961 Edinburgh)

QUERIES AND ANSWERS

Celluloid Splints

"J H L" inquires about the method of making the celluloid splints that are used for tuberculosis joints among other purposes

*** Pexuloid—non inflammable celluloid—splints were described in the journals by the late Dr F E Batten of the Children's Hospital, Great Ormond Street some years before the war Acetone is the solvent used not ether alcohol Certalmid which is stronger than pexuloid was introduced by the Pensions Ministry for artificial limbs The materials for making certalmid may be obtained from the General Surgical Company Ltd Glensurco House Rosebery Avenue E C 1 It is scarcely necessary to state that these materials are used in bandage form applied on plaster casts of the affected parts A final external varnish of celluloid solution is used as a finish

Alopecia Areata

Dr. J. SANDISON CRABBE (Birmingham), in reply to "A. A. H.," writes: I wonder if your correspondent among the "usual remedies" has tried strong doses of ultra-violet rays preceded by the high-frequency glass vacuum tube. I have rarely failed to bring hairs on alopecia patches after twelve treatments. It generally shows up about a month after the final treatment.

Vehicle Sickness

"S. C." writes: May I suggest that "Yorkshire" (June 24th, p. 1138) should try "vasano" tablets (Schering).

Income Tax

Life Assurance Allowance

"R. H. J." has an insurance policy which provides for (*a*) a pension (or cash payment) at 65, (*b*) £50 per annum from the date of death until the date at which he would have reached 65, plus a lump sum representing his aggregate contributions accumulated at 3 per cent. per annum, and (*c*) disablement benefit. What relief can he claim for income tax.

*** Where death benefits are combined with others in a policy the income tax relief extends only to that portion of the annual premiums which represents payment in respect of death risk. The benefits covered by (*a*) and (*c*) above appear to be outside the scope of the relief, and the question to be decided is how much of that part of the premium paid in respect of (*b*) relates to death risk. The "lump sum" payment is within that category, and in R. H. J.'s case the inspector of taxes is willing to make the allowance (subject to the usual statutory restrictions) in respect of that benefit. There is another aspect of the question however. The Income Tax Acts provide that the relief shall extend to payments in respect of a deferred annuity payable on the death of the insurer or his wife, provided that the benefits are due under policies for securing a capital sum at death (which is not the case here) or are "made in connexion with any superannuation or bona fide pension scheme for the benefit . . . of persons engaged in any particular . . . profession." Whether the claim to the relief is saved by the latter proviso we do not know, and we suggest that "R. H. J." should put himself into communication with the head office of the company in question and ascertain whether representations have been made to the Inland Revenue Department for a ruling that the company's policies are within that proviso. If so the claim to relief would be appreciably greater than the amount which the inspector of taxes is at present willing to allow.

LETTERS, NOTES, ETC.

The Ionosphere

Less than ten years ago the Post Office was attempting to link up the Empire with a series of wireless stations transmitting on very long wave-lengths and employing enormous power—500 or so amperes—in the aerial. Marconi's discovery of the beam system altered the whole situation, and to-day the bulk of wireless telegraphy and telephony round the world is done by means of very short waves projected in the required direction at a slight angle from the surface of the earth and reflected downwards again by ionized regions of the upper atmosphere. The system is incomparably better than the long-wave method, and uses less power, but it is still subject to unexplained interference and fading-out, which may at times impair its efficiency. The reason for this weakness is that the system depends on a reflecting surface, which varies from hour to hour and from place to place according to laws which physicists have hardly begun to understand. Several of the men who are busy charting these mysterious regions—which have been named by Mr. Watson Watt the "ionosphere" by analogy with atmosphere—met at the Royal Society recently to compare notes in a discussion. Professor E. V. Appleton, whose name has been closely associated with the ionosphere in the loose term "the Appleton layer," described some of the results of the continuous research which has been going on at Slough by the method of wireless wave exploration. When a wave of a certain frequency is projected vertically upwards and strikes an ionized layer corresponding to its frequency it will be reflected back, having undergone certain changes which betray certain facts about the conditions it has encountered on the journey. For instance, it will have taken a certain time which, multiplied by the speed of light, will give, not the actual height, but the equivalent height of the layer which has reflected it. Some echoes are split into doublets by the earth's magnetic field, one half being of left-handed and the other of right-handed polarization. If a series of signals at a given wave-length are sent up and the wave-length is gradually shortened, the echoes will continue to return until a certain frequency is reached, when they suddenly stop. This means that the particular ionized layer has been penetrated, because the ionic density is not sufficient to reflect waves of that frequency. If, now, the frequency is raised still further, another point will be reached at which echoes start to return again. They are now being reflected from a more remote region of three or four times as dense an ionization as the nearer one. If the frequency is increased still further the waves will penetrate the whole ionosphere and go out into space. The lower region, about 105 kilometres above the earth, is called E; the upper region, at about 180 kilometres, is called F. In addition, intermediate levers of lower ionization than the E region are sometimes detected, but only when the E region happens to be absent for some exceptional reason. The limitation of the method is that if there should be a region of low ionization above a region of high ionization it will remain undetected. There is a kind of ledge on the F region: as the frequency is raised the ionization is shown to increase rapidly, then not so rapidly for a while, then rapidly again. The activity of the ionization of these levels varies with the times of day, for it is produced by the ultra-violet light of the sun. It is greatest at noon and falls off towards sunset, the minimum being reached about midnight. Ionization starts to build up an hour or so before ground sunrise, when the light is already reaching the sky sixty or a hundred miles up. The activity is greater in summer than in winter, and probably also follows the "sun-spot cycle" of eleven years, over which the sun's rays reach a maximum and minimum intensity. Sometimes quite unexpectedly high values are detected: three or four times the normal ionization for the region, and sometimes a powerful E region appears in the middle of the night. This nocturnal activity seems to be due to some kind of radiation which is bent round the curve of the earth by the magnetic field, and the abnormal intensity sometimes recorded in the summer may be due to thundery conditions. During the last few weeks these values have often been noted. It is obvious that progress in this, almost the latest branch of physical research, must be very significant for the perfection of imperial wireless communication.

A.A. London Route Map

For the motorist who requires assistance when driving into or out of London, or for traversing the metropolis in any direction, the Automobile Association has issued a route map covering an area of twenty miles square. The scale is one inch to the mile, and it has been found possible to name all the streets shown so that they are readily identified, and the routes are classified into "London Exits," "Recommended Routes," and "Lesser Roads." In view of their importance as landmarks, bridges, level crossings, golf courses, war memorials, railway stations, tramlines, etc., are specially indicated, while the Ministry of Transport numbers are given. Any motorist may obtain a free copy on request from the A.A., Fanum House, New Coventry Street, W.1.

A Warning

The local police ask us to publish a warning notice about a man who is visiting doctors in the Manchester area requesting them to subscribe to an ex-service men's athletic sports club, with which is associated a team of boy scout boxers. The literature that he presents is cyclostyled, and if carefully looked at is obviously faked. The police and the different ex-service organizations are anxious to stop him, and any practitioner whom he visits would do well to notify the police.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 41, 42, 43, 44, 45, and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 23.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

16 Intravenous Injections of Alcohol in Septicaemias

It has been demonstrated that intravenous alcoholic injections in broncho-pulmonary suppurations involve no risk to the patient. M. HAMBURGER and GUÉRIN (*Presse Méd.*, March 8th, 1933, p. 375) draw attention to their use in septicaemias. They are, however, indicated only in grave cases of general infection after failure of the usual remedies. The effects of alcohol on the blood are governed by the strength of its dilution and the dosage. *In vitro*, alcohol causes either haemolysis or coagulation; weak dilutions produce neither reaction, concentrated solutions above 50 per cent. cause both, while those below 25 per cent. occasion haemolysis but no coagulation. *In vivo*, other conditions arise. To inject a given quantity of alcohol weak dilutions cannot be utilized owing to the great amount of fluid that would be necessary; too strong solutions are contraindicated owing to their local action; therefore only average dilutions should be used. The present authors employ dilutions of 33 per cent., a strength which is used also by Landau and his collaborators. Bär and some German authorities report cure in cases of puerperal fever after administering 30 per cent. solutions. The dose varies from a few to 200 c.cm. The benefits of this treatment are shown in two recorded cases, one of staphylococcal septicaemia of long evolution, the other of prolonged fever of unknown origin. To avoid coagulation of the blood in the syringe, admixture of the blood and alcohol must be guarded against; a wise precaution is to smear both needle and syringe with paraffin beforehand. Immediately following the injection, pain, often localized at the shoulder, is felt along the vein, but this rapidly disappears; facial redness, sweats, etc., appear only after large doses. The pain occasionally persists for one or two days, and thrombosis occurred in one case without causing any ill effects. Besides its favourable bactericidal and other properties, alcohol exerts a marked lymphagogic action. Resulting from this treatment the temperature falls by lysis and the blood becomes sterile. The injections should be given when rigors are present, and treatment should be instituted before any organic failing (cardiac, pulmonary, renal, or hepatic) appears.

17 Visceroptosis and Recessive Status Lymphaticus

H. A. HOUGHTON (*Med. Journ. and Record*, March 1st, 1933, p. 184) believes that visceroptosis is a manifestation of a biological deficiency. He classes it with status lymphaticus, vagotonia (autonomic imbalance), cardiovascular asthenia, Addison's disease, and other analogous states—all being associated, at least in part, with chromaffin (suprarenal medullary) deficiency. This may be due to maternal ante-natal infection—syphilitic, tuberculous, or streptococcal—or to acute infections in early life. Status lymphaticus is associated frequently with more obvious disorders—for example, hyperthyroidism, gastric ulcer, appendicitis, spondylolisthesis, chronic arthritis, and pulmonary tuberculosis, as well as various osseous deformities. Many observers have emphasized the relation of lymphatism to chromaffin deficiency; the enlarged thymus, narrowed thinned aorta, cardioptosis, and visceroptosis are pathognomonic. Thymic enlargement and hypertrophy of lymphoblastic tissue has been produced experimentally by suprarenal extirpation. The clinical syndrome termed "vagotonia" is associated with visceroptosis, status lymphaticus, splanchnic neurosis, and diminished suprarenal secretion. Visceroptosis is characterized by asthenia, effort-syndrome, and gastro-intestinal symptoms. The patient's attitude suggests fatigue, the thorax is long and narrow, the epigastric angle acute, and the abdomen protruding, although some patients have rounded contours and abundant superficial fat. These patients are very susceptible to focal and general infections, especially tuberculosis, appendicitis, and chronic arthritis. The cardiovascular system is labile; the patients faint easily; they suffer from "nervous asthma," coryza and other vasomotor disturbances, cold extremities with localized sweating and transient tachycardia, and hypotension. Such symptoms are especially common among mental defectives and psychotics of the schizoid type, alcoholics, criminals, and suicides. The normal involution of hypertrophied lymphoid tissue is delayed, but in those patients who survive the characteristic symptoms tend to disappear, the blood pressure rises, and the heart and aorta approach the normal in size and configuration.

18 Polyneuritis following an Abortifacient

J. J. WUITE (*Nederl. Tijdschr. v. Geneesk.*, February 18th, 1933, p. 795) records three cases, two of which occurred in unmarried women, of polyneuritis following the use of apiol as an abortifacient. Recent investigations at Amsterdam and Leyden have shown that it is not the apiol but the presence in it of tri-ortho-cresyl phosphate that produces the toxic effect. Apiol polyneuritis is thus very similar to the ginger paralysis caused in North America in 1930 by consumption of Jamaica sugar adulterated by tri-ortho-cresyl phosphate; it is manifested by symmetrical paralysis and atrophy, with reaction of degeneration at the distant ends of the extremities and diminution of the tendon reflexes. The sensory disturbance is merely subjective and is only present at the onset. The prognosis is unfavourable, as is shown by the fact that one of the patients who had been under observation for two years was still incapacitated. In this case the presence of a bilateral ankle-clonus indicated a spinal lesion. Wuite draws attention to the fact that the dangerous drug is still obtainable.

Surgery

19 Partial Pancreatectomy in Chronic Spontaneous Hypoglycaemia

E. HOLMAN and O. RAILSBACK (*Surg., Gynecol. and Obstet.*, March, 1933, p. 591) describe ten cases of hyperinsulinism and hypoglycaemia, due to such various causes as a metastasizing tumour or carcinoma of the islets of Langerhans, a benign tumour or adenoma of the islets of Langerhans, or an overactivity of an otherwise normal-appearing pancreas. Hyperinsulinism, with its concomitant hypoglycaemia, is insidiously progressive in its course, and is characterized by symptoms of weakness and exhaustion, nervous irritability, easy fatigability, extreme hunger, muscular twitchings and tremors, imperfect and hazy vision, diplopia, unsteadiness of gait, excessive perspiration, and loss of emotional control. Disorientation is also present in the more serious cases with epileptiform attacks, seizures, syncope, and semi-stuporous states leading to coma and finally death. It was found in nearly every case that frequent meals greatly relieved symptoms, however severe, and might even avert an attack. In all but two of the ten cases surgical treatment was carried out with varying results. In four instances an apparently normal pancreas was found and part of it excised to control the hyperinsulinism. In one of these cases a second operation was necessary to remove necrotic pancreatic tissue. In this case, and one other, definite improvement was noted, but the remaining two relapsed after operation and no final improvement was observed. It is suggested that in these four cases small adenomata in the remaining pancreas may have been overlooked, and it is therefore advisable to mobilize the pancreas fairly completely and to remove at least four-fifths of the gland.

Two patients died from coma before operation, and necropsy disclosed in one case an adenoma in the mid-portion of the pancreas and in the other a small carcinomatous tumour of the islets of Langerhans. In another case a nodular pancreas was found with nodules in the liver, but the patient died a month later of carcinoma of the islets with metastases to the liver. One of the most successful cases was that in which a small adenocarcinoma of the islets was removed from the mid-portion of the pancreas. The patient, a woman of 52, had no further attacks, and this constitutes the first recorded case of a cure of this type of lesion. Of the two remaining cases one had a tumour of β cells of the islets of Langerhans which was enucleated and the other an adenoma of the islets which was excised from the pancreas. No further attacks occurred after operation in either of these cases.

20 Fracture of Tibia with Dislocation of Fibula

M. HUARD (*Bull. et Mém. Soc. Nat. de Chir.*, April 1st, 1933, p. 487) discusses dislocation of the fibula associated with fracture of the tibia and reports four cases in which this occurred. In the majority of cases the dislocation takes place upwards or outwards, and only occasionally forwards. It may hinder the flexion of the knee and may be accompanied by injury to the external popliteal nerve. The fracture of the tibia may take place in any position and an incorrect position of the lower fragment may cause shortening of the limb. In cases of open fracture there is great danger of infection which may necessitate the amputation of the leg and may even cause the death of the patient. Treatment should begin as soon as possible, and should be preceded, in the first instance, by clinical and *x*-ray examination. The reduction of the dislocation should then be carried out, and it has been found that in some cases it is possible, by external manipulation, to reduce both the dislocation and the fracture at the same time. When this fails operation is necessary to reduce the fracture as this is of primary importance. In some instances the dislocation is overlooked at first, and a secondary operation may then be necessary to carry out resection of the head of the fibula. This is a simple procedure and gives good functional results. Where the external popliteal nerve has been involved exploration should be undertaken, followed by electrical treatment, which has proved most satisfactory.

21 Carcinoma of the Colon in a Young Woman

FRIART and RAHIER (*Le Scalpel*, March 18th, 1933, p. 377) report a case of carcinoma of the sigmoid colon in a girl of 26 years. Her symptoms were diarrhoea with vomiting and raised temperature. The abdomen was not distended, but the caecum was tender, borborygmi were present, and pain was felt on pressure over the descending colon. When next seen four days later the diarrhoea had stopped, the abdomen was distended, and considerable loss in weight had occurred. The acute symptoms subsided for about two months, but then recurred. A bismuth meal showed a marked dilatation of the small intestine, but there were no definite indications as to the nature of the obstruction, which was disclosed by a bismuth enema. Laparotomy was then carried out, and showed considerable dilatation of the small intestine—which was obstructed by a band of peritoneal adhesions—and a growth was felt in the sigmoid colon. Owing to the poor condition of the patient it was only possible to make a colostomy in the descending colon above the growth. The patient died, and necropsy showed a mass in the rectum, about 25 cm. from the anus, which was producing a stricture of the bowel. Histological examination of the growth showed this to be a colloid adenocarcinoma which had invaded and extended through the muscular wall of the bowel. There were no signs of metastasis. The unusual occurrence of a carcinoma of the bowel in a patient of 26 years of age and the slight nature of the symptoms make the case of special interest. It is suggested that if a sigmoidoscope had been used the nature of the condition might possibly have been ascertained prior to operation.

Therapeutics

22 Muscle Extract in Cardiovascular Disease

Recent researches suggest that in certain regions of the myocardium substances exist which excite or stimulate systole. P.-N. DESCHAMPS (*Arch. des Mal. du Cœur*, March, 1933, p. 223) reviews the present position thus: (1) "cardiac hormones are sought no longer in the myocardium, but in the skeletal muscles," (2) "the physiological and therapeutic action is definitely vaso-dilator, especially in the coronary arteries." Indications for administration are cardiac failure, arrhythmia, angina pectoris, intermittent claudication, and (occasionally) hypertension. The introduction of these extracts coincides with the discovery that pancreatic and liver extracts have similar vaso-dilator and cardiotonic properties. There is evidence that muscular exertion liberates antispasmodic and vaso-dilator substances, which sometimes prevent anginal attacks or intermittent claudication. Muscle extracts are useful chiefly in spasmodic angina. Attacks due to cardiac dilatation or coronary thrombosis are seldom if ever relieved. One writer reports that 73.5 per cent. of cases of angina were relieved. Those whose blood pressure was only slightly raised benefited most. In another series of eighteen cases twelve were greatly improved, three somewhat relieved, and a further three unrelieved. In addition to these vaso-dilator and antispasmodic effects muscle extracts appear to have a cardiotonic and regulating action, relieving decompensation and arrhythmia. The therapeutic action sometimes resembles that of digitalis. When muscle extract is combined with digitalis the effect is very definite. In two cases, extrasystoles of many years' duration disappeared. Another writer, however, found these extracts useful only in angina. The majority of writers confirm their utility in various arrhythmias. Of other substances "padutin," found in human urine and apparently of pancreatic origin, lowers dogs' blood pressure rapidly (after intravenous injection); and "eutonin" (liver extract) appears to relieve angina, but does not influence arterial tension and rhythm. Muscle extracts are given orally, intramuscularly, or intravenously. The daily dose is 50 to 80 drops. Prolonged treatment is necessary; afterwards, daily doses are reduced gradually to 10 drops or less. Some writers inject 17 minims intravenously in arrhythmia, hypertension, and angina. It produces a sense of warmth, flushing of face, and rapid fall in blood pressure (10 to 30 mm. Hg). No ill effects have occurred. The composition of these substances is uncertain. Many amino-acids have a similar cardiovascular action. A crystalline substance, "adenosine," obtained from muscle extracts, has a powerful vaso-dilator action on the coronary arteries of the guinea-pig.

23 Sodium Barbital in Whooping-cough

A. BREMS (*Ugeskrift for Laeger*, March 30th, 1933, p. 369) reports from the Blegdams Hospital in Denmark observations on the action of luminal (barbital) in about 100 cases of whooping-cough. Only 64 of these cases were, however, suitable for statistical analysis. The preparation used was in every case a 0.5 per cent. solution of sodium luminal. This solution contained 5 mg. per c.cm.—that is, about 2.50 cg. to the teaspoonful. Usually one teaspoonful was given three to six times a day, but this dosage was somewhat reduced for the youngest patients. Children tolerate luminal surprisingly well, and in several cases up to 15 cg. were given daily over a considerable period without any ill effects. In ten of the sixty-four cases the luminal was ineffective; in all the other cases it was more or less beneficial, reducing the violence of the coughing and vomiting. There were half a score of cases in which the relief from the symptoms obtained by this drug ceased when it was temporarily withheld. It was, however, difficult to measure accurately and numerically the degree of benefit derived from this treatment. One drawback to it was the frequency with which rashes broke

out in response to the comparatively high dosage. Among the sixty-four patients there were seven with luminal rashes which passed off when the drug was discontinued. A disconcerting feature of these rashes was their likeness to a measles rash. Marked drowsiness was observed in only three cases, although the exhibition of the drug was often continued a long time.

Ophthalmology

24 Retrobulbar Injections and Seventh Nerve Block

K. K. NAYAR and G. J. NAYUDU (*Brit. Journ. Ophthalmol.*, April, 1933, p. 233) have abandoned blocking the seventh nerve at the stylo-mastoid foramen in favour of O'Brien's method (*Arch. Ophthalmol.*, December, 1929). Observations on 5,000 cases of retrobulbar anaesthesia for various intraocular operations at the Government Ophthalmic Hospital, Madras, show that a 60-mm. dental syringe and a fine needle, 40 mm. long, using 1 c.cm. of a 4 per cent. novocain solution with a few drops of adrenaline, gives the best results. A larger or longer needle is more likely to cause retrobulbar haemorrhage. Paralysis or paresis of the inferor rectus muscle from gravitation of novocain to the floor of the orbit is annoying in cataract extraction, and is best avoided by keeping the needle towards the lateral orbital wall and tilting it slightly upward just before injection. Vomiting has not been experienced. Additional conjunctival anaesthesia is required in enucleation and evisceration.

25 Leber's Disease

L. S. PETRIGNANI (*Thèse de Paris*, 1933, No. 50), who records seven illustrative cases in patients aged from 11 to 32, states that Leber's disease, or familial and hereditary optic atrophy, does not always appear at puberty, but often first occurs at a more advanced age. Its onset is most frequent between 18 and 25. The extreme limits on record are 5 and 71. With rare exceptions the disease is transmitted by maternal heredity, but sometimes it may skip several generations. The essential sign is a central scotoma, which is always bilateral and is more extensive than that due to nicotine and alcohol. It is refractory to treatment of any kind. The central scotoma causes a considerable impairment of vision, but after some months' progress no further aggravation takes place, peripheral vision persists, and the atrophy never becomes complete. The ocular symptoms are often associated with other disturbances such as nervous disorders, which are almost constant, and including headache, change of character, psychical disturbance, epilepsy or epileptic equivalents, endocrine disorders, which are sometimes very marked, and delay in coagulation of the blood. The condition is a simple degeneration and not a post-inflammatory atrophy.

26 Spontaneous Detachment of the Retina

L. PAUFIQUE (*Journ. de Méd. de Lyon*, March, 1933, p. 189), in a review of this subject, states that in idiopathic detachment the vision rarely remains stationary, but progresses to total loss of vision. To effect a cure the hole in the retina must be closed. Though most common in myopes, the condition is frequently found in senile cases with vascular lesions. Inquiry must be made as to syphilis, state of the blood pressure, urine, and the presence of septic foci. Two theories of causation now hold the field. (1) The extravasation theory holds that the retina is detached by the formation of subretinal fluid consequent on choroido-retinal changes. The retina becomes thinned, and gives way at the summit of the extravasation. Analysis of the fluid shows blood pigment and a high percentage of albumin, which point to multiple minute haemorrhages and inflammation. The integrity of the vitreous has been repeatedly demonstrated histologically. (2) By the attraction theory, the formation of vitreous bands and the contraction of the vitreous tears the retina. Through this tear the fluid vitreous pours. The supporting histological evidence has been obtained from old myopic, or disorganized, eyes. The old forms of treatment are of no practical value. Modern operations include: Sourdille's, where multiple punctures are followed by the injection of mercuric cyanide (1 in 10,000), which necessitates several months in bed, is painful, and is only successful in incomplete detachments; Gonin's deep obliterative thermo-puncture, a tedious procedure sometimes followed by large intraocular haemorrhage; Lindner and Guist's, where 15 to 20 trephine holes are made, through which the choroid is cauterized with KOH, a long complicated method, often causing much reaction; diathermic coagulation, which is still in the experimental stage; and, finally, the author's subchoroidal galvano-cauterization. This aims at obtaining choroido-retinal adherence. The site for the operation is indicated by the retinal tear. Five to six careful incisions are made through the sclera, avoiding damage to the choroid, and the point of a galvano-cautery is inserted for two to three seconds. The method is rapid, the patient is only in bed fifteen days, and the results are very satisfactory.

Obstetrics and Gynaecology

27 Diagnosis of Ectopic Gestation

R. F. MATTERS (*Med. Journ. of Australia*, March 11th, 1933, p. 314) records two cases of ectopic gestation to illustrate the difficulties which may occur in reaching a diagnosis. The first patient had no vaginal bleeding nor alteration of her periods, while the second stated that she had been pregnant and had aborted. Doubt was engendered in this respect by her asking for curettage. The provisional diagnosis in the first case was ruptured gastric ulcer. She had severe abdominal pain with tenderness in the epigastrium and free fluid in the abdomen. On vaginal examination the uterus was not found to be enlarged, but there was a boggy fullness in the pouch of Douglas, and the tube, although not noticeably enlarged, was thickened. Palpation with the finger revealed pulsation here, and led to the correct diagnosis without the need of aspirating the posterior fornix, which felt like a retroflexed gravid uterus. The cervix appeared to be soft, but bimanual examination was difficult owing to the fat abdominal wall. Ectopic gestation or ovarian cyst was suspected. On laparotomy the mass was found to be a large unruptured haematosalpinx due to extrauterine pregnancy in the ampullary end of the right tube.

28 Relief of Post-castration Symptoms

A. A. WERNER and W. D. COLLIER (*Journ. Amer. Med. Assoc.*, March 4th, 1933, p. 633) report the effect of theelin injections on women after castration. Four women who had been subjected to complete bilateral oöphorectomy, the uterus being left intact, and one whose uterus had been removed, were given injections of this preparation each day, the doses rising from 4 c.cm. (equivalent to 200 rat units) to 8 c.cm. By means of light curettings uterine material was obtained for histological examination. All the patients had had most of the usual subjective symptoms—namely, nervousness, irritability, headaches, loss of memory, formication, hot flushes, vertigo, and circulatory irregularities. One patient was freed from them in about twenty days. Another had marked improvement after the ninth day, but later developed a sinus infection which caused some trouble. The third was obviously better by the sixth day, and felt normal within a fortnight. The fourth was free from symptoms after the sixth day, and the fifth patient after the seventh day. All had atrophy of the cervix and uterus, but theelin induced endometrial hyperplasia, which was apparent within three weeks. The stroma returned to its normal type and the epithelium became better differentiated. The endometrial thickening never exceeded that of the normal resting or interval stage, but bleeding occurred from it of a type

qualitatively indistinguishable from the menstrual flow in normal women, and accompanied by the usual subjective menstrual symptomatology. In four cases of ovariectomized women to whom large doses of theelin were given libido was markedly increased. Excessive intramuscular injections were given over a period of from eighty-three to ninety-three days without discomfort, until a daily dosage of 6 to 8 c.cm. was reached. The breasts were restored to an apparently normal state.

29 Aschheim-Zondek Reaction in Chorion-epithelioma

M. DAVEO (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, February, 1933, p. 215) illustrates by a case the great value of the Aschheim-Zondek reaction in complications following a mole, where histopathological examinations of the debris of curettage are often inadequate for a precocious diagnosis. The patient, aged 48 years, sought advice for troubles which she attributed to the menopause. Until four months previously menses had been regular and normal. Clinical examination revealed a softened cervix and a globular but very soft uterus. Twenty days later the patient had a severe haemorrhage and, when seen, was in labour. A complete mole was expelled. The uterine cavity was immediately explored, and a careful curettage made. Recovery was afebrile and the patient was up on the twelfth day, although the uterus appeared slightly subinvoluted. Five weeks after the expulsion of the mole the patient reported a loss of blood. On examination the uterus was found to be slightly enlarged and rather soft. A catheter specimen was immediately taken for an Aschheim-Zondek test. This was made according to Brouha's technique and was found to be strongly positive. A hysterectomy performed several days later confirmed the diagnosis of chorion-epithelioma. A small tumour the size of a grain of maize was found in an angle of the uterus. The patient made a good recovery.

Pathology

30 Effect of Typhoid Toxin on Leucocytes

Two years ago M. Coppo stated that a progressive left-handed shift of the polymorphonuclear count could be obtained *in vitro* by treating suspensions of leucocytes in serum with typhoid toxin. He suggested that this phenomenon was due to a reversal of the usual cell developmental process. D. R. CLIMENKO (*Lo Sperimentale*, March 30th, 1933, p. 96) considered this conclusion of doubtful validity, and, in view of the important clinical considerations involved, decided to repeat the investigation with certain additions. A left-handed deflection of the polymorphonuclear count was again observed, as described by Coppo, but this was shown to be unassociated with a developmental reversal. The cause appeared to be a differential destruction by autolysis of the granulocytes, the older cells yielding more swiftly than the younger cells. With the appearance of this deflection of the count there was a concomitant diminution in the total number of granulocytes present and a relative increase in the proportion of lymphocytes. When a suspension of leucocytes in a dilute typhoid toxin was watched on a warm stage, it was noticed that even in the course of the first few minutes the myelogenous elements began to manifest signs of destruction. Cells which had previously displayed amoeboid movement became rounded and stationary, the intracellular granular movement ceased, and the cell grew more opaque. A little later it broke down completely, being replaced by an amorphous mass of granular debris. The author never saw a lymphoid cell behave in this manner, and is convinced that they are not affected to the same extent by the toxin. Various authors have demonstrated the occurrence of a marked left-handed shift in cases of pyogenic infection—that is to say, in cases where there is a stimulation of phagocytic activity—and a consequent increase in the production and liberation of leucocytes. Substances such as gelatin, nucleic acid, and colchicine, which are known to induce a transient leucocytosis, have been shown by Ponder and Flint to bring about a concomitant regenerative shift of the count. Conversely, a right-handed shift is found in pernicious anaemia, lymphatic leukaemia, sprue, and aplastic anaemia, where the leucogenic activity of the bone marrow is depressed. The reaction concerned must be irreversible, according to Climenko, and Coppo's deductions of the possibility of transformation of a cell with a polymorphous nucleus into one with a simple nucleus be rejected. Typhoid toxin, being an active biological substance, quickens the process of autolysis, and introduces an element of differentiation in this respect between the behaviour of the two types of cells.

31 Study of Gliomas by Tissue Culture

DOROTHY S. RUSSELL and J. O. W. BLAND (*Journ. Path. and Bact.*, March, 1933, p. 273) records the results obtained from the tissue culture of a series of twenty gliomas. Active migration of tumour cells was obtained in a number of types. The cells exhibited great plasticity of form during migration, but preserved their morphological characters on coming to rest, thereby emphasizing the specificity of the different types. Actual multiplication of cells was conclusively demonstrated in two examples of spongioblastoma multiforme only. Suitable fragments were selected from material obtained from the operating theatre. Explants were cut with diameters of 1 to 1.5 mm., and mounted in the usual way in media, such as the expressed serum from the clot resulting from a mixture of two parts of heparinized human plasma with three parts of chick embryo extract. Other successful media were dilute human plasma (one part to two or three of embryo extract) and, to a less extent, hen plasma. Three examples of medulloblastoma were cultivated, but in only one was an adequate demonstration of migrating cells obtained. It proved to be a spindle cell, with scanty cytoplasm and a delicate process which extended from one or both poles of the nucleus, and frequently became attached by one or both of its processes to mesoblastic cells. No neuroblasts were detected. In one probable case of polar spongioblastoma the migrating cells closely resembled those of medulloblastoma, but the nuclei were usually slightly larger, the nucleoplasm was less densely haematoxyphil, and the [illegible] a little more bulky. In one case [illegible] the migrating cells were distinctive. Satisfactory migration was obtained in six out of seven specimens of spongioblastoma multiforme, some true growth being also observable. In three out of five cases of astrocytoma good migration was observed, typical astrocytes appearing. The development of neuroglial fibrils was demonstrated by phosphotungstic acid haematoxylin. No mitoses were seen. The authors enumerate certain features common to the different types successfully cultivated. The outgrowths in their general characters have more in common with cultures of mesoblastic tissues than with those of epithelia. The specificity of the different types of glioma was fairly clear. Cells such as astrocytes do not appear to have that special rigidity of form which has been claimed for them, an explanation in some measure of the highly infiltrative character of the gliomas as a group.

32 Bacteriology of Intestinal Infections in Infants

M. M. JOHNSTON, A. BROWN, and M. J. KAAKE (*Amer. Journ. Dis. Child.*, March, 1933, p. 498) made, in the autumn of 1930 and 1931, a bacteriological examination of the stools of 111 infants under 2 years of age, and of fifty-nine children aged from 2 to 12 years. They found dysentery and paratyphoid bacilli in 113 cases (approximately 67 per cent.). There were isolated thirty-six strains of *B. dysenteriae* Sonne, fifteen of *B. dysenteriae* Hiss-Russell, seventeen of *B. dysenteriae* Flexner, forty-seven of the Schmitz bacillus, twelve of *B. dispar*, five of *B. asiaticus*, and seven of *B. paratyphosus* B. Blood and pus accompanied the infection in a large proportion of cases. The writers suggest that flies may be the possible vector of these micro-organisms, which some domestic animals have been found to harbour.

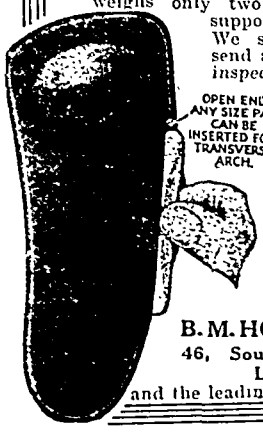
BRITISH MADE THROUGHOUT.

Trade **"HEPATAGEN"** *Mark*
(MIST. HEPATICA CONC. HEWLETT.)

Composition.—Ext. Cascarae, Ext. Rhei, Jalapin, Podophyllin, Cocainae Hydrochlor., 1-20th gr. in each fluid drachm.
This preparation does NOT come under the Dangerous Drugs Act.

A popular remedy for Chronic Biliousness, Catarrhal Jaundice, and the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, it has been used with marked benefit.

In the treatment of acute or temporary constipation, in convalescents, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.



The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz.; and 90-oz. Bottles. Price in England, 12/6 per pound.
This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

RENDLESHAM HALL.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. (Toll Call from London.)

Proprietors: The Norwood Sanatorium, Limited.

THE ROYAL EARLSWOOD INSTITUTION

FOR MENTAL DEFECTIVES, REDHILL, SURREY.

(Formerly the EARLSWOOD ASYLUM.)

FOR THOSE REQUIRING CONTROL with EXPERT SUPERVISION and needing SPECIAL TRAINING in useful occupations. *SCHOOLS, FARMING, and various TRADE WORKSHOPS.* Inclusive fees from £110 p.a. *THOSE UNABLE TO PAY* admitted by votes of subscribers, with part payment towards cost.

RECREATIONS: ALL outdoor games, EXCELLENT BAND by Male Staff, for Concerts Dancing, etc.

Apply, THE MEDICAL SUPERINTENDENT, Earlswood, Redhill, Surrey, or to the Secretary, Mr. H. STEPHENS, 14-16, Ludgate Hill, E.C.4.

ALCOHOLISM, NEURASTHENIA, Etc.

(For Men)

At this beautifully situated country mansion in Warwickshire (2 hrs. from London on L.M.S.R.), the residential treatment of Alcoholism, Neurasthenia, Insomnia, and Nervous breakdown is carried out on the most modern principles under the supervision of the Res. Med. Supt. Recreation and graduated occupational therapy are available in the extensive secluded grounds. Prospectus from A. E. CARVER, M.D., D.P.M., Resident Medical Superintendent.

ALCOHOLISM, DRUG HABIT, NEURASTHENIA, etc.

BAY MOUNT, PAIGNTON.

ESTABLISHED 1922. *Phone*: PAIGNTON 5110.

A comfortable private HOME, charmingly situated overlooking Torbay, near Torquay. Main line 3¼ hours from Paddington. Both Ladies and Gentlemen admitted as voluntary patients.

The treatment is the outcome of many years' experience, and besides removing all craving for drink and drugs, it has a tonic action on the system, and the general health is improved. Alcohol and drugs reduced gradually, without suffering.

FUNCTIONAL NERVOUS DISEASES AND NEURASTHENIA are also treated with excellent results. Cases with insomnia, depression, etc., do especially well.

Exceptionally good climate and ample and varied amusement. Moderate, inclusive terms. Prospectus, etc., from STANFORD PARR, M.B., Ch.B., Res. Med. Supt., Bay Mount, Paignton.

ALCOHOLISM & DRUG HABIT

DALRYMPLE HOUSE, RICKMANSWORTH, HERTS.

For the treatment of GENTLEMEN. Estab. 1883 by an Association of prominent medical men and others for the study and treatment of alcohol and drug abuse. Large secluded grounds on the bank of the River Colne. *Voluntary Patients can be received under the Inebriates Act.* Full-sized billiards, tennis, croquet, bowls. Golf (Moor Park, Sandy Lodge) close by. For partics. apply to—F. S. D. HOGG, M.R.C.S., &c., Resident Med. Supt. Telephone: 16 RICKMANSWORTH.

The MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.

Telephone: RODNEY 2101—4.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY received.

NEW OUT-PATIENTS: MEN — Mondays and Thursdays, 2 p.m. WOMEN—Tuesdays and Fridays, 2 p.m. CHILDREN—Mondays and Fridays, 10 a.m.

IN-PATIENTS: (*a*) 229 beds (both sexes) in wards or separate rooms, including 35 beds in a ward of King's College Hospital, which is in use as a temporary annex of the Maudsley Hospital. (*b*) 13 private rooms (for ladies) with special sitting rooms, garden, and dietary.

TERMS

(*a*) £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.

(*b*) £6 6s. a week.

Terms include (with rare exceptions) all forms of treatment, for which unusual facilities exist—there being a staff of consultant specialists; and the central laboratory of London County Mental Hospitals being attached to the Hospital.

Inquiries of EDWARD MAPOTHER, M.D., F.R.C.P., F.R.C.S., Medical Superintendent.

ALCOHOLISM & OTHER DRUG HABITS.

THE HARE NURSING HOME.

As founded and established by the late Dr. FRANCIS HARE, for 20 years Med. Supt. of the Norwood Sanatorium, and author of "Alcoholism," etc; for the treatment of ALCOHOLISM, other Drug Habits, Insomnia, Neurasthenia, Functional Nervous Disorders.

"THE OLD HILL HOUSE," CHISLEHURST, KENT.

Fees 5—10 guineas. Ample amusements. 25 bedrooms. Annexe for mild cases. Quiet and pleasant situation.

Ladies and gentlemen admitted for treatment. For prospectus, etc., write or 'phone WALTER F. MASTERS, M.D., M.R.C.S., D.P.H., Barrister at Law (Res. Med. Supt.). Author of "The Alcohol Habit."

'Phone: Chislehurst 451 *Telegrams*: "Masters," Chislehurst.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Diosrders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 59.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 24 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from *Northampton*, and 12 *miles* from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week.
Apply, Dr. D. E. M. DOUGLAS-MORRIS Telephone: Newport Pagnell 121.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES suffering from mental and nervous diseases, either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

Tele. Address: Triform, Wesdo—London.
Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Practices and Partnerships for Disposal. Full particulars sent free.

1. S.E. COAST.—SMALL SELECT RESIDENTIAL SEASIDE Resort.—PARTNERSHIP in well-established and easily worked Practice of £2,234 p.a. Panel about 700. Fees range from 3/6 to £1 1s. (chiefly 5/- to 10/6). Very little midwifery or night work. Handsome well-built detached house standing in its own grounds containing 4 bedrooms, etc., and with good garden and garage, etc., for sale. Partner should be aged 35-45 and hold London degree and be interested in games. Premium one-half share £2,250.

2. EAST ANGLIA.—PARTNERSHIP IN OLD-ESTABLISHED Country Practice of £2,750 p.a. in most beautiful part, easy distance of the coast. Panel 1,150. Fees 3/6 to £1 1s., medicine extra. Suitable house available. Small Cottage Hospital. Good scope for increase. Premium one-third share two years' purchase.

3. S. COAST.—RESIDENTIAL TOWN AND WATERING PLACE. —PARTNERSHIP in well-established Practice of about £1,500 p.a. Panel 1,500. No midwifery. Good house to purchase, or it might be let on lease. A one-half or three-fifths share would be sold at two years' purchase.

4. DEVONSHIRE.—WELL-ESTABLISHED COUNTRY PRACTICE in beautiful district near the Coast. Cash receipts average £1,376 p.a. Panel over 725. AGAROL

BRAND COMPOUND

FOR CONSTIPATION

"FOR better results"—is the watchword in producing Agarol. A mineral oil emulsion of highest grade ingredients obtainable, prepared with the efficiency of seasoned experience, cannot but be dependable. Its effectiveness is a reliable aid in teaching the intestinal tract to "keep hours," its exceptional palatability makes the taking of medicine easy and reasonably pleasant. § Agarol Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It contains no artificial flavouring, no sugar, alcohol, or alkali. Trial supply sent on request.

Bottles of 125 C.C.

TETANUS ANTITOXIN

Refined and Concentrated
(P., D. & Co.)

THE antitoxic constituents of anti-tetanus serum are associated with the pseudo-globulin proteins. The aim in concentrating an antitoxin is to present these pseudo-globulins as free as possible from the other constituents which are not only therapeutically valueless but are, moreover, believed to be the chief causes of protein sensitization and anaphylaxis.

Tetanus Antitoxin (P., D. & Co.) has been so concentrated and refined that these undesirable proteins have been reduced to an extremely low percentage. There is thus little fear of serum reaction, and no unpleasant urticaria is likely to follow injection. The very high concentration which has been achieved is also a considerable advantage in administering the large doses required for treatment.

Tetanus Antitoxin (P., D. & Co.), in addition to conforming to the stringent standards imposed on all P., D. & Co. biological preparations, is further tested in the Laboratory of the Inoculation Department, St. Mary's Hospital, London, W. (Founder: Sir Almroth E. Wright, M.D.), and certified as to potency, sterility, and freedom from excess of antiseptic.

Supplied in bulbs containing 1,000, 3,000, or 20,000 International units (equivalent to 500, 1,500 and 10,000 American units).

SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:
CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

Full particulars from
J. FLINT, "SANDOZ" PRODUCTS, 5, Wigmore Street, LONDON, W.1

Wholesale—
BROOKS & WARBURTON, Ltd., 232, Vauxhall Bridge Road, LONDON, S.W.

FOR BOILS

Whether there is a single boil or a multiplicity of furuncles, subcutaneous injections of EDWENIL will produce a prompt response.

If treated in the early stages, the boil or furuncle disappears without coming to maturity. In more mature lesions, the infections quickly come to a head, burst spontaneously, and are followed by a rapid recovery.

The time required for the complete resolving of even an extensive carbuncle is astonishingly short. Average dose: 2 c.c. daily to effect. EDWENIL is non-toxic and does not cause anaphylaxis.

EDWENIL

is a polyvalent antibacterial agent which is effective in all endotoxic infections. It is available in 2 c.c. ampoules and in bottles of 12½ and 25 c.c.

Made in the Laboratory of

E. H. SPICER & CO. LTD.

WATFORD, HERTS.

And at 72 WIGMORE STREET, LONDON, W.1.

SOME THOUGHTS ON

ASTHMA

By A. J. D. CAMERON, M.B., Ch.B.

Physician to the Sherwood Park Clinic and Spa, Tunbridge Wells.

With a Foreword by

KENNETH PLAYFAIR, M.A., M.B., B.Ch., M.R.C.P.

The records of many years of labour and researches begun at Preston Deanery Hall and now an important feature at Sherwood Park, Tunbridge Wells.

FIFTH EDITION. Fully Revised and Enlarged. Crown 8vo. Pp. 1,048. 21/- net; post. 9d.

SYNOPSIS OF

MEDICINE

By H. LETHEBY TIDY, M.A., M.D., B.Ch.Oxon., F.R.C.P.Lond.

Physician, St. Thomas's Hospital; Consulting Physician, Royal Northern Hospital

"An admirable *index medicus*. . . The scope is far wider than in the majority of books. Throughout, "treatment" meets with ample consideration . . this fact alone will enhance its value enormously for the busy practitioner"—*British Medical Journal.*

"We can say without hesitation that the book is far ahead of any medical synopsis it has been our lot to encounter"—*Lancet*

Bristol: JOHN WRIGHT & SONS LTD. [Illustrated Catalogue free.] **London: SIMPKIN MARSHALL LTD.**

HEFFER PUBLICATIONS

PRACTICAL PHYSIOLOGICAL CHEMISTRY

By S. W. COLE, M.A., University Lecturer in Medical Chemistry, Cambridge.

9th Edition. Demy 8vo. Cloth. Illustrated. 12s. 6d. net (Postage 9d.).

This edition has been carefully revised and practically rewritten. By the use of a new type, and a new arrangement of the text and formulae, both the size and price of the book have been decreased, whilst its value as a book of reference has been greatly enhanced.

Ready September. **FUNDAMENTALS OF BIOCHEMISTRY IN RELATION TO HUMAN PHYSIOLOGY**

By T. R. PARSONS, B.Sc.(Lond.), M.A.(Cantab.).

Crown 8vo. Cloth. 4th Revised Edition. Illustrated. 10s. 6d. net (Postage 6d.).

Since this book was last revised the science of Biochemistry itself has made enormous strides. The new edition of this volume attempts to bring the subject matter absolutely up to date.

BASIC GERMAN FOR SCIENCE STUDENTS With Vocabulary and English Translations of the German Passages.

By M. L. BARKER, M.A., Ph.D., Lecturer in German, University of Edinburgh.

Demy 8vo. Cloth. 6s. net (Postage 6d.). (Eight-page Prospectus on application).

"Will meet the need of many who wish to acquire quickly a working knowledge of this language in order to study German books and periodicals of a scientific nature."—BRITISH MEDICAL JOURNAL.

What did your wife think of the June heat wave?...

. . . Probably without saying very much about it, she was wishing she had a Frigidaire.

Why don't you give her one?

Wouldn't your food be better for keeping in Frigidaire's crisp, frosty cold? Think of milk kept in an ordinary larder this weather! Kept in Frigidaire it would be safer—healthier. Think of the ice cream and frozen sweets you could have . . . all the ice cubes for cool drinks . . . the crisp salads tasting as though they had just been picked from a shady garden . . . the tempting cold entrees and savouries . . . the cool, juicy fruit . . . firm, dewy butter.

Food kept in Frigidaire tastes better and looks more appetising. You know better than most men the importance of that. You also know the importance of preserving the vitamin content—and the value of refrigeration in that respect. We make no extravagant claims for Frigidaire; but it does keep good food good.

Why don't you invest in one? Our new plan calls for a capital outlay of only £5. A postcard to our Bond Street showrooms brings you full information about a suitable cabinet.

CELLANBAND PASTE BANDAGES

for

VARICOSE ULCERATION OR PHLEBITIS

The Antiseptic Paste-Impregnated Bandages prepared in accordance with the Formula mentioned in the "B.M.J.," Oct. 4th, 1930.

An efficient treatment for Varicose Ulcers, Varicose Veins, Phlebitis, Swellings, Strains, Dislocations, and the like.

The speediest treatment, too, for they enable the convalescent to resume reasonable light duties at a much earlier period than in the past.

Lead to rapid reduction of Oedema through the very marked dehydrating and antiphlogistic effect they bring about.

CELLANBAND BANDAGES measure 7 yards, thus affording ample length for the "Heelcap" and "Stirrup" pieces as illustrated, the application of which before winding so greatly increases the supporting power of the Bandage.

12/- per doz. Sample 1/- post free. Descriptive literature on request.

Nutritional Anaemia
does not occur in Almata-fed babies

As many as 45 per cent. of breast fed babies and 51 per cent. of those artificially fed have been found to suffer from nutritional anæmia, and it is stated that the incidence of this can be considerably reduced by the addition of iron to the diet. (*Vide* M. of H. Circ. 1290, d/- 27.10.32.)

Almata contains ingredients which are *naturally* rich in iron, and therefore the addition of this in the form of mineral salts is unnecessary.

Almata is a *complete* food for infants, and nursing mothers also derive the utmost benefit from taking it.

Sold by all Chemists. **ALMATA** KEEN'S COMPLETE FOOD *Price 2/1 and 4/- per tin.*

A trial sample together with the Almata book will be gladly sent post free to doctors.
Write to Keen, Robinson & Co., Ltd. (Dept. A.18), Carrow Works, Norwich.

FELLOWS

(TRADE MARK)

IRON
SODIUM
POTASSIUM
PHOSPHORUS
MANGANESE
CALCIUM

to overcome the marked mineral depletions caused by such acute infections as acute bronchitis, coryza, the debility of old age, and postoperative conditions.

Compound Syrup of Hypophosphites "Fellows" contains all the essential elements in a perfectly balanced solution. Unbalanced cell metabolism induced by a depleted mineral content is speedily overcome when these elements are supplied in a form which the body can readily assimilate.

Compound Syrup of Hypophosphites "Fellows" does this effectively. It therefore becomes the one most valuable preparation in these conditions.

Suggested dose: One teaspoonful three times a day well mixed with water.

The Treatment of Macrocytic Anæmias with MARMITE

Reports of clinical trials published recently (The Lancet, June 17th, 1933, p. 1283) afford striking confirmatory evidence of the hæmopoietic properties of Marmite.

Reference is made by the author of these reports to the successful results obtained by several other investigators who have used Marmite in various macrocytic anæmias—including the anæmia associated with cœliac disease and with sprue, as well as in true pernicious anæmia.

It is interesting to note that other yeast preparations and Vitamin B concentrates proved to be inactive curatively when tested on a number of cases of tropical macrocytic anæmia, but that these cases all responded to Marmite treatment. This observation on the superiority of Marmite as an anti-anæmic agent is in agreement with the findings of workers in other fields (Archives of Disease in Childhood, April, 1933) and tends to show that Marmite is of even more value as a medicament than was recognised hitherto.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7

Works: KING'S LANGLEY, HERTFORDSHIRE.

M233

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

"EVIPAN" (SODIUM)

INTRAVENOUSLY

Recent developments in anaesthesia have been directed towards sparing the patient unnecessary apprehension and fear—that is, psychic trauma. And in this direction the greatest success has been achieved by the rectal and intravenous administration of basal anaesthetics. But the anaesthesia obtained with those now in use (*e.g.*, Avertin) is of prolonged duration—what has been lacking is a substance which, with no disturbance of the patient's psyche, would give short, full anaesthesia **sufficient in itself** for minor surgery and the surgery of accidents.

With '**Evipan**' **Sodium**, given intravenously, this gap has been filled.

'Evipan' sodium is the soluble salt of a cyclo-hexenyl barbiturate; **its characteristic feature is the extreme rapidity with which it is detoxicated in the organism.**

2 to 10 c.c. of a 10 per cent. 'Evipan' sodium solution, intravenously, will give full anaesthesia for 5 to 30 minutes, according to the dosage.

'Evipan' sodium for "short anaesthesia" has been tested clinically and pharmacologically by the Anaesthetics Committee of the Medical Research Council, whose report appears in *The Lancet* of July 1st, 1933, p 43. Also, *ibid.*, there is a detailed account* of 100 cases of 'Evipan' sodium anaesthesia, with appropriate dosage, in:—

sections for biopsy	dilatation and curettage
extraction of teeth	tonsillectomy
removal of nails	diathermy
oesophagoscopy	dental cystectomy
bronchoscopy	partial mammectomy
radium insertions	appendicectomy
ureteric catheterisation	presacral sympathectomy
cystodiathermy	nephrectomy
sigmoidoscopy	bilateral inguinal hernia
ligation of haemorrhoids	empyema
operations for fistula	etc., etc.

*Evipan. An Intravenous Anaesthetic. By Ronald Jarman, D.S.C., M.R.C.S.Eng., and A. Lawrence Abel, M.S.Lond., F.R.C.S.Eng.—*The Lancet*, July 1st, 1933, p. 18.

'Evipan' Sodium is issued in boxes containing 5 ampoules of 1.0 g. powder and 5 ampoules of 10.5 c.c. distilled water. Price 12/6 per box, subject to usual discount.

'Evipan' is the registered trade mark denoting the brand of N-methyl-cyclo-hexenyl-methyl barbituric acid.

Tensile strength and Elasticity

The longbow-man of the Robin Hood period was particularly careful that his bow-string was of the necessary tensile strength and elasticity.

More vital still to the surgeon is the tensile strength and elasticity of the catgut ligature and suture that he uses. A slipped ligature or the breakdown of a suture may be fatal.

THE TENSILE STRENGTH AND ELASTICITY OF LONDON HOSPITAL CATGUT being distinguishing features, the surgeon can employ it with every confidence.

CARBON DIOXIDE in General Practice

An Easily Portable Apparatus

Sparklet Pocket Resuscitator ("J" Size)

CARBON DIOXIDE (CO_2), and OXYGEN & CARBON DIOXIDE MIXTURE, are now becoming more and more generally used, not only in all forms of respiratory emergencies, but in the routine treatment of chronic respiratory diseases such as ASTHMA, HAY FEVER, PNEUMONIA, WHOOPING COUGH, etc., etc.

In the past, these gases have only been available in cumbersome cylinders, so that the CARBON DIOXIDE, or GAS MIXTURE treatment, has often been difficult and expensive.

NOW, however, a simple compact apparatus is available in the Sparklet "POCKET RESUSCITATOR" (here illustrated). Measuring only 10 inches long, it can be carried in the handbag; a turn of a lever **instantly** releasing the requisite stream of pure CARBON DIOXIDE, OXYGEN, or MIXTURE GAS when and where needed.

THE SPARKLET POCKET RESUSCITATOR

Make your own
CO_2 SNOW PENCILS

By using the CO_2 SNOW ADAPTOR in conjunction with the RESUSCITATOR HOLDER, CO_2 Snow Pencils are produced Instantly—Anywhere—At Low Cost—for the treatment of NAEVI, LUPUS, WARTS, and other Skin Blemishes.

(PRICES in British Isles)

RESUSCITATOR "J" Size, as illustrated, **32/6**

GLAND THERAPY

BY MEANS OF

MEMBROIDS

A new form of capsule which is proof against gastric juices

Membroids possess considerable advantage over keratin-coated tablets, the medicaments being in loose powder form, and therefore more easily absorbed, a noteworthy factor considering that Membroids do not disintegrate until they have passed through the stomach. All gland substances are available in Membroids form. It is only necessary for the Physician to add **MEMBROIDS "EVANS"** to his prescription for any of the standard formulæ

A list of Membroidal Products will be sent by return on request

For the Premature
and
Undeveloped Infant

By reason of its balanced content of Vitamins A, B_1, B_2, and D, Radio-Malt presents an ideal medium for the administration of all these four vitamins in accurately-measured amounts to infants born before term and to those which are weak and under-developed.

This fact was demonstrated recently in the case of an infant, weighing only 1 lb. at birth, which, according to the physician, was reared entirely on milk with Radio-Malt as an adjuvant. Within three months its weight had increased to $5\frac{1}{2}$ lb., and its progress was satisfactory in every way.

Radio-Malt is valuable also to normal children because it provides properly-balanced and standardised amounts of Vitamins A, B_1, B_2, and D, the supply of which in the ordinary dietary is often inadequate for the daily requirement.

OESTROFORM

Oestroform is the pure crystalline ovarian follicular hormone. It is available for clinical use in sterile solution for injection, and in tablets for oral administration; both forms are accurately standardised and are of exceptionally high unitage, the solution possessing an activity of 1000 units per c.c. and the tablets an activity of 1000 units per tablet.

The value of Oestroform in the various conditions associated with metabolic disturbances of ovarian origin has been demonstrated recently by exhaustive clinical tests.

For example, in the treatment of vomiting of pregnancy, some very promising results have been obtained with Oestroform, great relief having been experienced by the injection of a fairly large dose—10,000 units three times per week (for this purpose a special solution is available).

In menopausal disorders also, Oestroform administration is proving to be of considerable value.

PART OF AN ANCIENT EGYPTIAN PRESCRIPTION FOR DRIVING AWAY AN INFANTILE AILMENT BY AN EXORCISM ACCOMPANIED BY THE EATING OF A COOKED MOUSE.—An incantation for the cure of a sick child is followed by further directions in the words here reproduced from a magico-medical papyrus: "Let the child, or his mother, eat a cooked mouse. Hang the bones round his neck with fine linen in which seven knots have been tied." Remains of mice have been found in the alimentary canals of children buried at least 6000 years ago. It is clear in each case that the mouse had been eaten after having been skinned. For children *in extremis* a mouse was a very common remedy in the East in much later times and the custom is still known in Europe.

ON

THE UNITY OF GASTRIC DISORDERS *

BY

ARTHUR F. HURST, M.A., M.D.OXON., F.R.C.P.

SENIOR PHYSICIAN TO GUY'S HOSPITAL

I. THE HYPERSTHENIC AND HYPOSTHENIC GASTRIC CONSTITUTIONS

Investigations on the anatomy and physiology of the stomach of healthy young adults of both sexes show that considerable variations from the average occur under perfectly normal conditions. In about 80 per cent. these variations fall within comparatively narrow limits. This is shown, for example, in the results obtained by Bennett and Ryle (1921) with a fractional gruel test meal in a hundred healthy male students who had never suffered from any form of indigestion: the curves of free hydrochloric acid in eighty of them fell within the shaded area shown in Figs. 1, 3, and 4. The anatomy and physiology of the stomach in these 80 per cent. of healthy people are so perfectly adjusted to the exigencies of ordinary life that they are likely to reach old age without ever suffering from any form of chronic gastric disorder. Of the remaining 20 per cent., approximately one-half are born with what I have called the hypersthenic gastric constitution, and most of the other half with a hyposthenic gastric constitution—both conditions being often familial. The former have hyperchlorhydria (Fig. 1), which is often, though not invariably, associated with a short, high, rapidly emptying stomach. The latter have hypochlorhydria, which is generally associated with a long, low, slowly emptying stomach. Both constitutions are compatible with perfect health, but in unfavourable circumstances each predisposes to the development of certain organic diseases. In addition to the hyposthenic diathesis, about 3 per cent. of normal individuals have complete achylia gastrica—an inborn error of secretion—which is even more frequently familial than hyperchlorhydria and hypochlorhydria (Fig. 2).

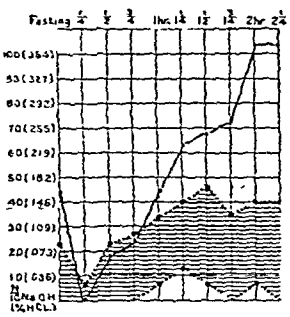

FIG. 1.—Test meal of one of the ten with hyperchlorhydria in Bennett and Ryle's 100 healthy students

It has been suggested that Bennett and Ryle's group of healthy medical students cannot be regarded as an average sample of the population, as healthy people of all ages should be included. But if, as I believe, constitutional hyperchlorhydria and constitutional hypochlorhydria predispose to a variety of diseases, including gastric and duodenal ulcer, carcinoma of the stomach, and Addison's anaemia, which become more and more frequent as age advances, it is clear that the younger the group of healthy individuals examined the fairer sample they will be of the general population before it has become affected with diseases acquired as a result of constitutional predisposition. Thus very few of a hundred unselected young men with constitutional hyperchlorhydria, who may eventually develop gastric or duodenal ulcer, and none of those with constitutional hypochlorhydria who may later develop carcinoma of the stomach or Addison's anaemia, have already symptoms of these conditions; so that the hundred selected healthy young men will be fair samples of the total male population of their age. On the other hand, if the subsequent history of the hundred could be traced, from what is known of the incidence of these diseases about 11.5 per cent. would develop one or other of them, and almost all of these would be among the constitutional hyperchlorhydrias and hypochlorhydrias. Consequently a large group comprising healthy people of all ages, such as that investigated by Vanzant, Alvarez, and their colleagues (1932), is a selected group from which many of the individuals with the hypersthenic and hyposthenic gastric constitutions are excluded, and an inaccurate picture of their incidence is obtained, quite apart from the fact that owing to the effect of long-continued gastritis the number of people with acquired low acidity makes it impossible to estimate the true incidence of constitutional hypochlorhydria.

The secretion of mucus is the normal response of every healthy mucous membrane to chemical, thermal, and mechanical irritants. The presence of mucus in the ordinary fractional test meal is, however, an indication that gastritis is present, because nothing could be less irritating than the gruel meal. But it is a matter of common experience that mucus is rarely present in much excess, except in patients with hypochlorhydria or achlorhydria. This is due to the fact that the hypersthenic stomach is capable of secreting very little mucus compared with the hyposthenic stomach, whether in response to an irritant or as a result of inflammation (Bonis).

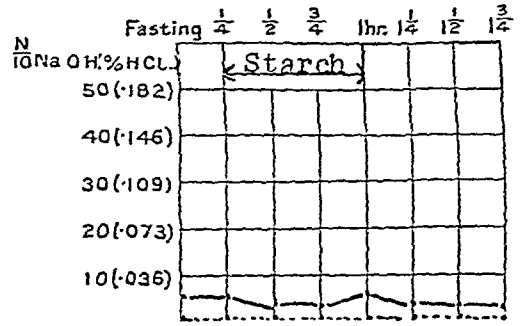

FIG. 2.—Test meal of one of the four with achlorhydria in Bennett and Ryle's 100 healthy students.

II. CAUSES OF GASTRIC DISORDERS

(A) MECHANICAL, CHEMICAL, AND THERMAL IRRITANTS

The mouth acts as the first line of defence in protecting the alimentary tract from damage by swallowed irritants. Food and drink are brought to the body temperature, chemical irritants are diluted, and lumps of food are broken up by chewing, and are intimately mixed with saliva, which softens hard particles and coats insoluble ones with mucus. An individual with good teeth, who takes the trouble to use them, and avoids grossly indigestible food and excess of alcohol, need not swallow anything until its thermal, chemical, and mechanical properties have been so altered that it will cause no irritation when it comes into contact with the gastric mucous membrane.

Though the majority of people are provided with a first line of defence which is potentially adequate, comparatively few make sufficiently good use of it. Food is swallowed without being properly chewed, with the result that the stomach is daily subjected to mechanical, chemical, and thermal irritants. It is also often damaged by excessive indulgence in alcohol, or by taking cocktails or spirits whilst fasting, when even a small quantity acts as a powerful irritant. Strong tea and coffee, curry and other spices, condiments, pickles, and excess of totally indigestible raw vegetable matter, taken in the mistaken idea that plenty of "roughage" is good for the health,

* Delivered at Washington on May 8th, 1933, before the American Gastro-Enterological Society.

may have the same effect. The stomach is frequently irritated by the unconscious swallowing of the "juice" of tobacco smoked in excess. Many people injure their gastric mucous membrane by taking drugs—often quite needlessly—for supposed constipation, rheumatism, and other self-diagnosed complaints, quite apart from those used in the treatment of definite chronic maladies, such as bromides, iodides, salicylates, mercury, digitalis, creosote, and copaiba. The contents of the duodenum and the upper end of the jejunum are gastric irritants. Gastritis is therefore a constant sequel of gastro-jejunostomy and partial gastrectomy, and is in fact partly responsible for the success of these operations, as it is an important factor in the reduction of the free acid present. Fortunately the gastritis is often completely latent, although it is a cause of post-operative symptoms much more frequently than is generally believed.

The stomach acts as a very efficient second line of defence for protecting the small intestine from irritation. Very hot and very cold food and drink are brought to the body temperature, and the gastric juice dilutes chemical irritants, such as alcohol, and softens hard particles. Peristalsis in the distal half of the stomach conveys the food to the pyloric sphincter, which does not relax if the food is insufficiently broken up, so that a churning process results, which does its inadequate best to perform the functions which the teeth should have carried out. The stomach, and especially the pyloric half in which the mucous membrane is most exposed to friction, is thus liable to suffer in its attempt to protect the small intestine. In the 80 per cent. of people with an average type of stomach the irritation of the mucous membrane is reduced to a minimum. In the 10 per cent. with constitutional hyperchlorhydria there is ample protection against mechanical irritants, and also against chemical irritants if taken when the stomach is full. But as hyperchlorhydria is generally associated with rapid evacuation, the stomach is empty for a much longer proportion of the day and night than in the average individual, so that there is more opportunity for the mucous membrane to be damaged by alcohol, tobacco, and drugs. In the 10 per cent. with constitutional hypochlorhydria and achylia the second line of defence is deficient; they are consequently very likely to develop gastritis, and in most cases the hypochlorhydria sooner or later gives place to achlorhydria. This is in spite of the attempt made by the stomach to protect itself by the secretion of mucus; but it is a remarkable fact that the type of stomach which, on account of its deficiency in gastric juice, most often requires a protective coating of mucus is the one which, as I have already pointed out, is most capable of producing it.

(B) INFECTION

Infected material is constantly swallowed by people with pyorrhoea alveolaris, infected tonsils, chronic pharyngitis, and sinusitis, and by children with adenoids. In achlorhydria, whether due to primary achylia, or secondary to chronic gastritis in individuals with constitutional hypochlorhydria, the antiseptic acid barrier of the stomach is lost, and streptococcal infection of the inflamed, and therefore abnormally vulnerable, mucous membrane of the stomach is very likely to occur. This is especially true for the most advanced stages of gastritis, in which the atrophy involves not only the secreting tubules but also the mucin-secreting cells, so that the mucous membrane is no longer protected from invasion by bacteria by a layer of mucus. In such cases a fractional test meal shows the absence of mucus as well as gastric juice. When gastric juice is secreted in normal or excessive quantities, and even when it is deficient in hypochlorhydria, swallowed bacteria are rapidly destroyed.

(C) HAEMATOGENOUS IRRITANTS

Many acute infections are accompanied by acute gastritis, which is often followed by chronic gastritis (Faber). This must be due mainly to the direct action of bacterial toxins conveyed in the blood to the gastric mucous membrane, which perhaps makes an attempt to excrete them. Possibly the toxins produced in the body tissues themselves in acute infections may be in part responsible (Kauffmann, 1929), just as the toxins of uraemia and those produced in the skin in extensive burns may cause gastro-duodenitis and acute ulcers. The vomiting in scarlet fever and the abdominal symptoms in gastric influenza are the result of acute gastritis, and acute ulcers and erosions are often found in the stomach and duodenum in fatal cases of a great variety of infections. The development of acute haematogenous gastritis is probably quite independent of any special type of gastric constitution, though it is only likely to become chronic in individuals with hyperchlorhydria, hypochlorhydria, or achlorhydria.

The causes of gastritis are so numerous and so common that few people can pass through life without being subjected to one or more of them. Fortunately the 80 per cent. of individuals with the average normal stomach are so well protected that they rarely develop gastritis as a result of these insults, but few of those with constitutional hyperchlorhydria and constitutional hypochlorhydria escape.

Faber (1908) was the first to show how common chronic gastritis is by injecting formalin into the abdomen immediately after death, in order to prevent the post-mortem changes, which had hitherto made it impossible to carry out satisfactory investigations on the condition of the gastric mucous membrane with necropsy material. Three lines of investigation have confirmed and extended his work—biopsy, gastroscopy, and radiology. Konjetzny has examined a very large number of specimens prepared immediately after partial gastrectomy, which he performs for all kinds of gastric disorders, whether there is external evidence of disease or not. Though his work appears to be totally unjustifiable surgically, it has led to results of the greatest interest and importance from a scientific point of view, as he has found various degrees of gastritis in every case. The results have been confirmed by many others, who have performed similar operations for patients with ulcer symptoms, whether an ulcer was found or not. Further confirmation comes from Professor M. J. Stewart of Leeds, and Dr. Keith Simpson at Guy's Hospital, in the investigation of specimens obtained by partial gastrectomy performed for ulcer or carcinoma, and of fragments of mucous membrane obtained from the edge of the stoma in the performance of gastro-jejunostomy for duodenal ulcer and pyloric ulcer. Schindler, Korbsch, Hohlweg, and Gutzeit have improved the technique of gastroscopy to such a degree that they have been able to perform several hundred examinations without any ill result. Though it is unlikely that the method will ever become widely used, it has led to the accumulation of a great deal of very valuable information about the appearance of the gastric mucous membrane in various disorders. It has been of special value when it has been possible to compare the gastroscopic and radiological appearances of the same case.

Lastly, the improved radiological technique, which we owe primarily to Forssell, and which has been specially developed by Berg, has led to the study of the folds of gastric mucous membrane and the recognition of departures from the normal associated with different varieties of gastritis.

III. EFFECT OF GASTRITIS ON GASTRIC SECRETION

The functional efficiency of an organ is always reduced when it is inflamed. In acute gastritis no gastric juice is secreted. This was admirably demonstrated by Beaumont (1833) in his observations on the effect of a drinking bout on Alexis St. Martin. In chronic gastritis the secretion is reduced to an extent which varies with the severity and the duration of the inflammation, the actual

amount of free acid present in the stomach in a test meal depending upon the constitutional type of stomach in each individual. Thus the hyperchlorhydria of individuals with the hypersthenic gastric constitution becomes less extreme, or may be replaced by a normal curve of acidity, or even, in exceptional cases, by hypochlorhydria. This is well seen in the gastritis accompanying chronic ulcer, as when medical treatment has resulted in the healing of the ulcer and the disappearance of the gastritis the acidity is almost always higher than it was before. Thus in sixteen cases of gastric ulcer and thirty-two of duodenal ulcer under my care, in which a second test meal was given at the end of treatment, the acidity had increased in all but eight, and six of these already had hyperchlorhydria and two high normal curves. The gastric cases comprised one achlorhydria which became hypochlorhydria, five high normals which became hyperchlorhydria, and one which remained unchanged, and five hyperchlorhydria, three of which became still higher, two remaining unaltered (Fig. 3). Of the duodenal cases one with hypochlorhydria became a high normal and one an extreme hyperchlorhydria, two low normals became high normals, one normal became high normal, and one

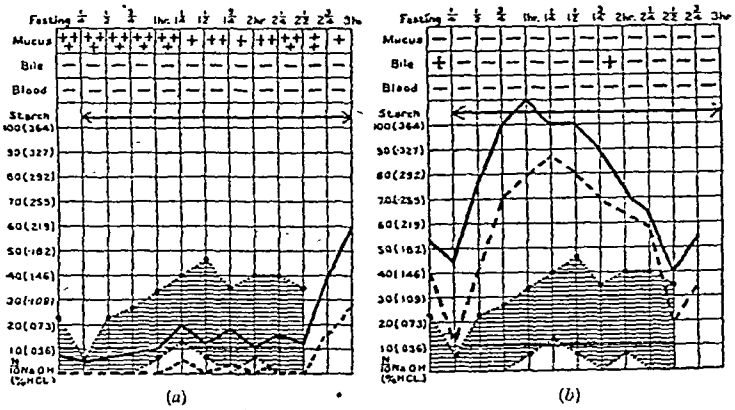

FIG. 3.—Duodenal ulcer with chronic gastritis. (*a*) July 20th, 1923; hypochlorhydria. (*b*) August 17th, 1928; after a month's treatment, gastritis disappeared and ulcer healed; hyperchlorhydria unmasked.

became hyperchlorhydria, seven high normals became hyperchlorhydria and one remained unaltered, and of twelve hyperchlorhydria eight became still higher, four remaining unaltered (Hurst and Venables, 1929).

The hypochlorhydria of individuals with the hyposthenic gastric constitution is almost always replaced eventually by complete achlorhydria. In most cases this can be overcome by removal of the exciting causes, an unirritating diet, and lavage every morning with dilute hydrogen peroxide. Thus in 82 per cent. of thirty-four of my cases of achlorhydria treated in this way free acid returned (Hartfall, 1932) (Fig. 4). The reduction in acidity in these cases is mainly due, as it is in hyperchlorhydria, to the effect of the inflammation on the activity of the secreting glands, but it is increased as a result of the excessive secretion of mucus which accompanies the inflammation. The mucus acts partly by its mechanical action in blocking the mouths of the secreting tubules and partly by its chemical action in combining with some of the free acid. The neutralizing effect is, however, comparatively slight, and due almost entirely to the sodium bicarbonate it contains and not to its own buffer action, as it almost completely disappears after the salt has been separated by dialysis (Bonis, 1930; Mitchell, 1931). In the 18 per cent. of cases in which the achlorhydria persisted after treatment the gastritis had presumably led to such a profound change in the gastric mucosa that recovery was impossible, and complete and permanent achylia resulted. It is clear that gastritis associated with high or normal acidity, so-called acid gastritis, is not an early stage of gastritis associated with achlorhydria, as has been suggested by Faber, Zweig, and others, nor is the former a result of prepyloric gastritis and the latter of fundus gastritis, as has been suggested by Porges and others. Both are due to the same causes, the amount of free acid depending upon the constitution of the individual concerned.

(A) GASTRITIS WITH CONSTITUTIONAL HYPERCHLORHYDRIA

I have already pointed out that hyperchlorhydria tends to protect the stomach from irritation when the first line of defence is inadequate. But the deleterious effect of friction on the mucous membrane of the distal half of the stomach when hard or large pieces of food are swallowed continues, and irritation by alcohol, tobacco, and drugs may occur during the many hours in which the stomach is empty. If even a mild degree of gastritis results from this, the mere presence of hyperchlorhydria is likely to aggravate it, as, although hyperchlorhydria is not itself a pathological condition, the excessive acidity

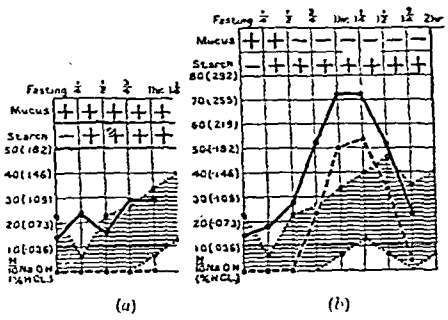

FIG. 4.—(*a*) Test meal in a case of Addison's anaemia on January 9th, showing achlorhydria and excess of mucus. (*b*) Test meal on April 2nd, showing normal acidity, and excess of mucus in only two fractions, after treatment by gastric lavage.

of the gastric juice is a potential danger. The healthy mucous membrane is always bathed in gastric juice, which is neither digested by its pepsin nor irritated by its free hydrochloric acid. After death, however, the mucous membrane is rapidly digested. During life localized necrotic areas may also undergo digestion, and possibly this also occurs in areas in which the circulation is temporarily arrested or very deficient before actual necrosis has occurred As peptic digestion is no more active with 0.3 per cent. than with 0.08 per cent. free hydrochloric acid, such digestion is not specially likely to occur in the presence of hyperchlorhydria. But although the living mucous membrane, even when abnormally vulnerable as a result of gastritis, can never undergo peptic digestion, it is very likely to be damaged by free hydrochloric acid if present in a strength greater than the average. The likelihood of this is still greater when the hyperchlorhydria is associated with hypersecretion, in which unusually strong acid continues to be secreted in the absence of food, which under ordinary conditions dilutes it and to some extent neutralizes it, owing to its alkaline reaction. According to Winkelstein (1933), the stomach secretes acid throughout the night in patients with ulcer, but never in normal people. Moreover, owing to the deficient power of secreting mucus, which is a characteristic of the hypersthenic stomach, the protection against damage afforded by a layer of mucus in the hyposthenic stomach is absent. It has been suggested that

the absence of mucus is due to its digestion by gastric juice, but mucus differs from other proteins in the extreme slowness with which it undergoes peptic digestion, and there is generally less organically combined hydrochloric acid with hyperchlorhydria than with the average normal acidity.

In the conditions already described, in which the failure of the first line of defence gives rise to chronic gastritis, the excessive acid in hyperchlorhydria gives the gastritis certain characteristics which are absent from that associated with hypochlorhydria and achlorhydria. It is very frequently associated with minute erosions, some of which may develop into acute ulcers, which may in turn become chronic ulcers. The condition may therefore be called ulcerative gastritis. When the hyperchlorhydria is associated with the rapidly emptying, short, high stomach which is often a feature of the hypersthenic gastric constitution, the duodenal bulb is equally involved, the condition thus being one of ulcerative gastro-duodenitis, in which a chronic ulcer is most likely to develop in the duodenum. When, on the other hand, the hyperchlorhydria is associated with a long, low, slowly emptying stomach, the main stress falls upon the stomach; the gastritis is likely to be more severe and a gastric ulcer may develop, whilst the duodenum is spared. At the same time the gastric stasis leads to more prolonged contact of the entire gastric mucous membrane with any irritants it may contain, so that although the distal half of the stomach is still the part most severely inflamed, the fundus is more affected than in duodenal ulcer. Consequently, the power of secreting acids by the fundus glands may be directly impaired, while their stimulation is reduced owing to the deficient production of the gastric hormone by the antral mucous membrane in response to chemical and reflex stimulation. In gastric ulcer the hyperchlorhydria which is at first present thus tends to be more or less reduced, and in very chronic cases hypochlorhydria, and very rarely even achlorhydria, may result. With treatment, however, the acidity always rises, though sufficient permanent damage may have taken place to prevent a return to the original hyperchlorhydria. Owing to the familial incidence of the hypersthenic gastric diathesis it is common for gastric or duodenal ulcers to occur in several members of the same family (Hurst and Stewart, 1929).

It is interesting to note that both Hart (1919) in Germany and Stewart (1929) in England found chronic gastric or duodenal ulcers or scars of such ulcers in about 10 per cent. of all necropsies, this being also approximately the number of healthy young adults with hyperchlorhydria. It would appear, therefore, that an individual with the hypersthenic gastric constitution is almost certain sooner or later to develop an ulcer, though I have seen two men and one woman over 70 years of age with an extreme degree of hyperchlorhydria who had never had a symptom or sign of ulcer or any form of indigestion. It is true that hyperchlorhydria may no longer be present when a test meal is given, especially in the case of a gastric ulcer, but it was probably present when the ulcer first formed, perhaps many years earlier, and has since been masked by the coexistent chronic gastritis.

(B) GASTRITIS WITH CONSTITUTIONAL HYPOCHLORHYDRIA AND ACHLORHYDRIA

Bennett and Ryle found that already at the age of 20 4 per cent. of one hundred healthy students had achlorhydria, which must have been due either to constitutional achylia gastrica or latent chronic gastritis. Hartfall has recently analysed the results of fractional test meals given to 2,448 of my private patients. Excluding twenty cases of achlorhydria artificially produced by gastro-jejunostomy, twenty-one cases associated with carcinoma of the stomach, and fifty-one with Addison's anaemia, there remain 2,356 patients, of whom 242 (10.3 per cent.) had achlorhydria. From 10 to 19 the incidence was 4 per cent., which is identical with that found by Bennett and Ryle in their normal students; there was a rise of 4 per cent. to the 30-39 period, and the same rise to the 40-49 period, but in the next three decades taken together there was a rise of only about 4 per cent. It can thus be concluded that all, or very nearly all, of the individuals with the hyposthenic gastric constitution, as well as a few with normal acidity, eventually develop achlorhydria as a result of gastritis. Gastritis with achlorhydria generally gives rise to no gastric symptoms, though it may occasionally produce a mild form of chronic indigestion, and it is not an uncommon cause of nausea.

In achlorhydria the excess of mucus is a poor substitute for gastric juice, and the consequent loss of the second line of defence leads to irritation of the small intestine, so that duodenitis and enteritis develop in addition to the gastritis. The mechanical and chemical irritation of the intestines explains why chronic and recurrent diarrhoea is often caused by achlorhydria, although in the majority of patients with achlorhydria the bowels are regular.

Swallowed bacteria flourish in the alkaline contents of the stomach, and may invade the mucous membrane, producing an infective gastritis, which may ultimately lead to atrophy of the mucous membrane. They also pass into the duodenum, which is normally sterile, but now swarms with bacteria. Knott (1927) has shown that the increased alkalinity of the intestinal contents allows bacteria which are normally confined to the colon to ascend the small intestine as far as the duodenum and stomach, both of which contain colon bacilli from the large intestine even more frequently than streptococci from the mouth. Chronic cholecystitis is generally a result of an ascending *B. coli* infection of the gall-bladder, which is especially likely to occur in the presence of achlorhydria (Hurst, 1932). This explains why free hydrochloric acid is absent from the stomach in about 50 per cent. of patients with gall-stones (Bonar, 1922). Achlorhydria is also a very important predisposing cause of intestinal infections, such as typhoid and paratyphoid fever, bacillary and amoebic dysentery, and cholera—the organisms of which are rapidly destroyed by the normal gastric juice—and its presence is therefore a constant source of danger to residents in tropical countries (Camps). The toxaemia which follows the intestinal infection resulting from achlorhydria is one factor in about 25 per cent. of cases of rheumatoid arthritis (Hurst, 1925; Miller and Smith, 1927), and in some cases of asthma, skin diseases, and other conditions associated with allergy, especially in children (Bray, 1931).

IV. EFFECTS OF GASTRITIS ON HAEMATOPOIESIS AND THE NUTRITION OF THE CENTRAL NERVOUS SYSTEM

The absence of free acid from the gastric contents may interfere with the assimilation of the iron in food, so that in individuals who take a diet in which there is only just enough iron for the needs of the body under the most favourable conditions of assimilation a simple achlorhydric anaemia develops (Faber, 1908), which differs from Addisonian (pernicious) anaemia in occurring almost exclusively in women, in whom menorrhagia is often a contributory factor, and in being curable by large doses of iron, whilst liver and stomach extract are entirely without effect (Witts, 1930).

Achlorhydria is found in about 99 per cent. of cases of the Addison's anaemia-subacute combined degeneration of the spinal cord syndrome, though it is now known that it is not the actual cause of it, the

absence of hydrochloric acid from the gastric secretion being associated with the absence of a substance, Castle's "intrinsic factor," required for the production of the natural stimulant of haematopoiesis and of another required for the normal nutrition of the central nervous system. The gastritis is the primary condition; there is, consequently, often a history of chronic diarrhoea or other symptoms to which it has given rise, dating from months or years before the onset of anaemic or nervous symptoms, and in several cases the achlorhydria has been known to exist during this time. The frequent occurrence of Addison's anaemia and subacute combined degeneration of the cord in more than one member of a family is due to the familial occurrence of constitutional achylia gastrica and hypochlorhydria, which predispose to severe gastritis. Moreover, achylia is often present without any abnormality of the blood or central nervous system in relatives of patients with these diseases (Hurst, 1927; Conner, 1930; Wilkinson and Brockbank, 1930).

The first function of the gastric mucous membrane to suffer in gastritis is the secretion of hydrochloric acid. Consequently, in the majority of cases of achlorhydria pepsin is still secreted in normal quantity, the secretion of mucus is actually increased, and the production of the haematopoietic intrinsic factor is unimpaired. If the exciting cause of the gastritis continues to be at work when complete achlorhydria has developed, the gastritis becomes progressively more severe, especially if large numbers of virulent streptococci are swallowed from the mouth or throat. After a time the damage to the secreting tubules is so profound that they can never recover their power of secreting acid, even if all active inflammation ceases, and at the same time the secretion of pepsin becomes more or less impaired. The mucus-secreting cells take part in the general atrophic changes of the mucous membrane, so that mucus disappears from the test meal, its absence being a sign of the severity of the process, and not an indication that no gastritis is present. In this advanced stage of gastritis the intrinsic factors required for the normal activity of the bone marrow and nutrition of the central nervous system may ceased to be formed, and Addison's anaemia and subacute combined degeneration of the cord develop. In a small number of cases this function of the mucous membrane is impaired at an earlier stage; thus in three of my cases of Addison's anaemia the secretion of free acid returned as a result of treatment of the gastritis, and six other similar cases have now been recorded. Moreover, in about 1 per cent. of cases of Addison's anaemia and subacute combined degeneration of the cord free hydrochloric acid is secreted. The haematopoietic and neurotrophic functions of the gastric mucous membrane are occasionally destroyed suddenly by an exceptionally severe attack of acute gastritis, the symptoms dating from an attack of food or corrosive poisoning, or from an acute infection (Hurst, 1926).

V. CARCINOMA OF THE STOMACH

I believe that carcinoma never develops in a normal stomach (1929). There is much evidence to show that in most of the 35 per cent. of cases in which free hydrochloric acid is present the carcinoma is secondary to chronic gastric ulcer. On the other hand, in the 65 per cent. of cases with achlorhydria the latter is a result of the associated gastritis and not of the carcinoma, and the carcinoma is probably a result of malignant degeneration of the chronically inflamed mucous membrane. Thus I have never seen a case—and I know of very few—in which achlorhydria has developed in a patient with carcinoma of the stomach, who was known to have free acid present at an earlier stage of the disease, although the secondary gastritis which must result from large ulcerated growths and the progressive destruction of the mucous membrane in extensive carcinoma would make it natural that such a change should occasionally be observed. There was no diminution in acidity in the three cases of gastric ulcer I have seen in which a test meal was given both before and after the onset of malignant degeneration. In one patient with ulcer-cancer who was kept comfortable by occasional lavage and an unirritating diet, the acidity actually rose in the course of six months. Polland and Bloomfield (1931) have recorded two similar cases. On the other hand, I have seen one case, and at least twenty others have been recorded, in which achlorhydria was known to be present from three to fifteen years before the development of cancer associated with achlorhydria.

Free hydrochloric acid is present in nearly all cases of carcinoma in which examination of the specimen obtained at operation shows unmistakable signs of originating in ulcer, whereas it is absent, and more extensive chronic gastritis is found, where no such signs are present. When a long history suggestive of ulcer is obtained free acid is generally present, but when the history is short and the carcinoma appears to be "primary" achlorhydria is found. The prospects of long survival after gastrectomy are better in cases with achlorhydria than with free acid (Hartman, 1921), though the reverse would be the case did those with achlorhydria represent a later stage of the same condition as those with free acid. Moreover, there is no relation between the size of a growth and the presence of achlorhydria, free acid being occasionally present with large inoperable growths and achlorhydria with very small, early, and removable ones (Polland and Bloomfield). I have seen a number of cases in which carcinoma of the stomach was preceded or accompanied by the development of Addison's anaemia or subacute combined degeneration of the cord, the gastritis having led to lack of the "intrinsic factor," and so caused the anaemia quite independently of undergoing malignant degeneration. It seems likely, indeed, that the incidence of carcinoma of the stomach in patients with Addison's anaemia, who are kept free from symptoms as a result of modern methods of treatment, will be abnormally high unless the associated gastritis is treated in spite of the absence of digestive symptoms.

CONCLUSIONS

I have brought forward evidence to show that the main organic disorders of the stomach ultimately depend upon the same exciting causes, which are so widespread in their incidence that very few people can reach old age without coming under the influence of one or more of them at some time in their lives. Fortunately, however, four-fifths of the population have stomachs which are endowed with sufficient resistance to escape damage, and it is only the remaining 20 per cent. who are likely, sooner or later, to develop some organic gastric disease.

If these views are correct, gastritis, gastric and duodenal ulcer, and carcinoma of the stomach could be prevented by the adoption of the simple hygienic measures required to avoid the exciting causes I have enumerated. It is, perhaps, too much a counsel of perfection to expect universal prophylaxis of this kind, but it might at any rate be provided for those people who can be recognized from their physical characteristics, or from their family histories, as being constitutionally liable to develop organic disease of the stomach.

Lastly, gastritis and gastric ulcer should be recognized much more frequently and at an earlier stage than in the past, and instead of simply dealing with the results of the former, such as achlorhydria or anaemia, the primary disease itself should also be treated, and steps taken to prevent its recurrence. We may thus hope that the

frequent failure of the physician to recognize cancer of the stomach sufficiently early for the surgeon to effect a cure will in the future be immaterial, owing to the success of the practitioner in preventing its development.

TREATMENT OF CHRONIC INFLAMMATORY DISEASES OF THE MOUTH, PHARYNX, AND LARYNX BY LOCAL APPLICATION OF ULTRA-VIOLET RAYS

BY

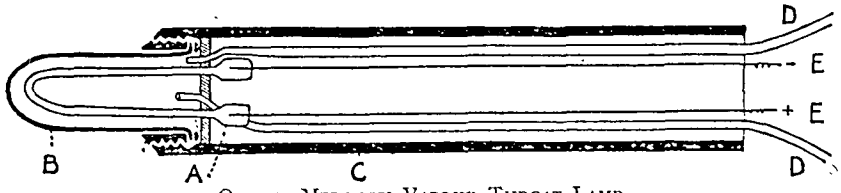
ALBERT EIDINOW, M.B., B.S.LOND.

PHYSICIAN IN CHARGE OF THE LIGHT DEPARTMENT, LONDON CLINIC AND INSTITUTE OF PHYSICAL MEDICINE, PIMLICO, AND TO THE RADIUM INSTITUTE, LONDON

The object of this paper is to record some results following the treatment of inflammatory diseases of the mucous membrane of the mouth, pharynx, and larynx by means of the local application of ultra-violet rays emitted by a specially designed "throat lamp."

During the past fifteen years Strandberg, working at the Finsen Light Institute at Copenhagen, has recorded successful results in the treatment of tuberculous disease of the larynx, following the exposure of the skin of the whole body by general irradiation to the ultra-violet rays of the carbon arc. Cemach and de Wesselow have designed special quartz rod applicators attached to the water-cooled Kromayer lamp or to the carbon arc of the Finsen type, for the local application of ultra-violet rays to the larynx. Similar quartz silvered mirrors for the reflection of rays and other apparatus have been designed. All these apparatuses are cumbersome, and necessitate long exposures to the source of light, and this makes treatment tedious and tiresome for the sick patient.

In 1926 I designed a small water-cooled quartz mercury vapour lamp for the direct application of ultra-violet rays to the buccal cavity, the tongue, pharynx, and larynx. This apparatus was demonstrated in 1929 to the Section of Laryngology of the Royal Society of Medicine. Since then I have treated over sixty patients. The technique which is described is based [illegible] and observations made during [illegible] cases.



The pathologic[illegible] Ryle found that already at the age of [illegible] may be classified [illegible] one hundred healthy students had a[illegible] ...ydria, which must have been due either to constituti[illegible] achylia gastrica or latent chronic gastritis. Hartfall recently analysed the results of fractional test meals given to 2,448 of my private patients. Excluding twenty cases of achlorhydria artificially produced by gastro-jejunostomy, so-called twenty-one cases associated with carcinoma of the stomach.

The value and scope of the treatment of many diseases of the mouth, pharynx, and throat by local ultra-violet irradiation is as yet little known to many oral surgeons and laryngologists. It is hoped that the extended clinical trial of this technique of treatment will confirm my results, and help to establish a valuable additional method of treatment for lesions which often resist other established methods.

TECHNIQUE OF METHOD

THE APPARATUS

This throat lamp was designed so that it could be easily inserted into the mouth, and could be brought by direct application to the pillars of the fauces, the post-nasal space, the pharynx, or the larynx. The lamp is essentially a small water-cooled "vacuum type" quartz mercury vapour lamp, and consists of three parts: (1) a quartz mercury vapour vacuum high-pressure burner; (2) a quartz water-jacket; and (3) a metal jacket, to which the burner is cemented, and which contains water-cooling apparatus, and also insulated leads carrying the electric current. The quartz burner is U-shaped and bent at its horizontal axis to an angle of 160 degrees. It is made of a thick-walled quartz tubing about 1.5 mm. in diameter. The internal diameter of the quartz tubing is 0.5 cm. One of the limbs of the U-tube is dilated at its terminal end. The burner is constructed on the same principle as the high-pressure-vacuum mercury vapour lamp, and operates on an electric current of 1 to 1.5 amperes and 80 to 120 volts between the electrodes (direct current only). The water-jacket is made of quartz, and is the shape and size of the adult thumb. It fits over the quartz burner and is oval in shape, measuring 6 × 3 × 2 cm., leaving a space of 0.5 cm. surrounding the quartz burner in every direction. The jacket is made to taper gradually as its closed extremity; the open end is widened and made circular, so that it can fit tightly to the metal holder by means of a rubber washer and a circular screw cap. The jacket can easily be removed, and in this way the quartz burner can be thoroughly cleaned and a differently shaped jacket can be attached when necessary. The metal holder is made of nickel-plated metal and is circular in shape, roughly 3 cm. in diameter and 15 cm. in length. The quartz burner is soldered and cemented into this holder, and the electrodes are carried through it, being well insulated with rubber and non-conducting composition, and fused to two copper electric wires, also well insulated, so

as to carry the electric current from the electrodes and burner In this way the conducting leads and electrodes are thoroughly insulated and made watertight Two metal tubes 3 mm in diameter are also carried through the metal holder for the circulation of water and cooling of the burner One is an inlet tube, and passes into the cavity of the water-jacket for 3 to 4 mm , the other is an outlet tube The inlet tube is connected by strong rubber tubing to a water tap, and the outlet tube has a rubber tube passing to a sink or basin In a recent model apparatus I have designed an electrical motor water pump is connected to a reservoir containing distilled water, and thus the lamp is cooled by the motor pump forcing water through its inlet and outlet tubes The circulation of water must be thoroughly efficient, and the lamp must be tested every time before it is used for treatment It must be perfectly cold when grasped by the hand after running for five to ten minutes The danger of overheating or insufficient cooling of the lamp is important, for as a result the mucous membrane may be damaged and seriously burned Further, the lamp will be overrun and the seals of the electrodes will melt and be destroyed It is herefore essential to carefully check the cooling mechanism of the lamp

Physical Nature of Rays Emitted

The lamp emits luminous and ultra violet rays of wavelength from about 8,000 to 2,300 A U The infra red and heat rays are completely absorbed by efficient water circulation The spectrum of the lamp has the same characters as the quartz mercury vapour lamp, but is of relatively weaker intensity, since only an electric current of 80 to 100 volts and one ampere is transmitted For this reason it is seen that the shorter ultra violet rays in the region of wave length 2,500 A U are relatively weaker in intensity and the longer ultra violet rays in the region of wave length 2,700 A U are stronger in intensity than those usually transmitted by the ordinary mercury vapour lamps working at an electrical potential of 2 5 amperes and 150 volts

Manipulation of Lamp

Before the lamp is started the water is made to circulate and completely fill the jacket , all air bubbles must be cleared The current is switched on and the lamp started by tilting the arc should burn evenly in both limbs of the U tube, and if the mercury column is uneven the lamp should be switched off and restarted until the columns are even and equal in both limbs After it has been running steadily in a horizontal position for two to three minutes the arc is established, and the lamp will then keep alight when held in any position Its outer surface must always be thoroughly clean; and this can be secured by employing a weak solution of acid, which must be washed and cleared by water before use Rays from either the upper or lower surfaces, or the end of the lamp, can be used alone, by covering the remaining portions with small pieces of lead foil fixed by elastic bands This is useful when only the tongue, palate, or the right or left tonsillar fossa is to be irradiated , the remaining areas of mucous membrane can be easily protected from the rays by such simple means After treatment is completed the lamp is cleaned by washing in water and rectified spirit, and then allowed to burn for two or three minutes, for the ultra-violet rays emitted have direct bactericidal action, and in this way the lamp is automatically efficiently sterilized

Details of Administration

The area which is to be irradiated and the surrounding mucous membrane of the pharangeal wall should be anaesthetized by a local anaesthetic I usually employ a 5 per cent or 10 per cent solution of cocaine hydrochloride in saline sprayed on the mucosa by means of a Devilbiss spray attached to a motor air pump This is a rapid and efficient method, and local swabbing of the mucosa or local injection of the palate or pillars of the fauces is rarely necessary The use of synthetic anaesthetics such as novutox, etc , is not suitable for the purposes of ultra-violet therapy, as they contain a quinoline base and other chemical compounds, which absorb short ultra violet rays and inhibit their biological action on the mucosa The operator should always wear an efficient mask and a pair of spectacles, so as to be protected from any sudden spasm of coughing, and also from the ultra violet rays which might otherwise cause inflammatory reaction of the conjunctiva The patient should wear a pair of dark tinted spectacles to protect the eyes against the irritative action of ultra violet rays , he should be seated in a comfortable rather low chair, be put at ease, and made to relax as much as possible The operator should stand facing the patient The operative procedure should be fully explained beforehand, so as to obtain the help and co operation of the patient during the treatment The patient is told to open the mouth and protrude the tongue, and to breathe deeply and slowly through the mouth The tongue is grasped with the thumb and middle finger of the left hand and firmly supported The lamp is now directed towards the base of the tongue or to the lesion, and as the grasp of the tongue is relaxed the lamp is finally placed in contact with the lesion, and simultaneously the patient is told to withdraw the tongue Once the lamp is in its proper position the patient's head is bent forward and downward and the lips are made to enclose the lamp This procedure should take less than five seconds, and should be carried out so as to avoid any retching, coughing, or straining The patient is then made to relax as much as possible and to take slow, deep breaths through the mouth, in harmony with the operator, who counts aloud with each inspiration In this way the dosage is checked and regulated by the operator, though it should also be checked by means of a time clock If the patient is uncomfortable, and coughs or strains, the lamp should be withdrawn and the whole procedure be started *de novo* A little education and encouragement soon makes the technique of treatment a comfortable and fairly simple procedure

Dosage and Effects

The mucous membrane of the buccal and pharyngeal cavities is three to four times as sensitive to ultra violet rays as the normal white skin By direct contact of this quartz lamp to the normal white skin an erythema reaction is produced after sixty seconds' exposure The erythema dose for the normal mucous membrane is ten to fifteen seconds This dose of ultra violet rays applied to the mucous membrane of the posterior pharyngeal wall or to the pillars of the fauces, will cause a visible redness of the mucosa twenty four to forty eight hours after irradiation After treatment the patient will experience a dryness and irritation of the throat, somewhat similar to a sore throat, and swallowing may be painful The reaction starts after a latent period of twelve hours and increases to its maximum after forty eight hours when it gradually subsides More intensive reactions occur with increased dosage or abnormal sensitiveness of mucosa This is seen in a diffuse redness, swelling and oedema, and the mucosa may gradually become increasingly oedematous The swelling may spread to the uvula the pillars of the fauces and in the larynx and may even cause oedema of the vocal cords and epiglottis Th reaction reaches a maximum after forty eight hours a

makes swallowing painful, with irritation of the throat. This intensive reaction may cause general malaise and pyrexia (100°–101° F.), and in such cases the patient should be put to bed at rest for twenty-four to forty-eight hours, and a menthol carbolic gargle and a light, semi-solid, tepid or cold diet prescribed. The oedema invariably subsides after forty-eight hours, and so far has never needed any other treatment.

This reaction is more common when treating subacute inflammatory conditions of the pharynx or tonsils, or when intensive treatment is applied in tuberculous lesions. Some types of the haemolytic streptococcal infections of the mucosa may give rise to a severe reaction, even with mild irradiation, and may cause redness and oedema of the whole palate, and severe reaction for twenty-four hours. Similar reactions have been observed in cases of Vincent's angina, but often the presence of chronic disease of tonsils and hidden septic crypts may cause this undue reaction. The mucosa of the patient who has a " gouty diathesis," with a markedly acid saliva, is often more sensitive to ultra-violet rays than others, and in such cases treatment must be started with extreme caution, with half or a quarter " mucosa erythema " dosage. It is better to give treatment daily or on alternate days in these types of sensitive cases, and gradually work up to the erythema reaction, for the sudden acute reaction may be alarming and distressing to the patient. When this severe reaction subsides beneficial results may follow. After the erythema reaction the mucous membrane settles to normal within five to seven days, and shows a rapid hardening to ultra-violet rays, inasmuch as the dosage at the second, and subsequent, treatment may be increased to 15-30-60 seconds, and only cause mild inflammatory reactions. In the treatment of chronic tuberculous and other inflammatory conditions of the palate and larynx a full erythema and blistering dose of rays is intentionally applied locally at the site of the lesion, all other areas being shielded from the rays by covering the lamp with metal foil. Following the oedema and erythema of the mucosa round the site of the lesion, a yellow white slough may appear five to six days later, which gradually separates within ten to fourteen days. The exudative reaction is obtained with twice or three times the average erythema dose, but dosage must be carefully controlled and determined by the density and infiltration of scar tissue, and the nature of the ulceration at the site of the lesion. Enlargement and swelling of the cervical lymph glands may follow from intensive local irradiation of the mucosa. This subsides within five to seven days. The painful symptoms following the application of ultra-violet rays may be relieved by the local application of infra-red and luminous rays to the skin area of the neck at the site of pain.

The subsequent dosage is increased according to the technique of treatment which is to be adopted. The first treatment is applied so as to test the sensitiveness of the mucosa to ultra-violet rays, and the dosage is accordingly controlled by these observations. Intensive local treatment is applied once every seven to fourteen days, varying with the duration and severity of the reactions following irradiation. When intensive treatment is applied the patient must be warned, and adequate arrangements for rest in bed, careful nursing, and diet may be necessary. Intensive local treatment should not be applied unless the general resistance of the patient is fairly good, as constitutional reactions may follow. In such cases I usually advise general ultra-violet irradiation of the body two or three times a week for two weeks prior to the application of the local irradiation treatment to the throat. In the cases which have been under my care I have only experienced severe constitutional reactions after treatment of subacute tuberculous disease of the larynx, associated with miliary dissemination of active tuberculous disease of the lungs, and I am now of the opinion that such cases are unsuitable for local irradiation therapy.

THERAPEUTIC ACTION ON MUCOUS MEMBRANE

The reaction of the tissues following the absorption of ultra-violet rays may cause gradual healing of a diseased lesion, owing to the local changes in the capillary blood vessels. A prolonged hyperaemia and vaso-dilatation is produced for five to seven days following irradiation; this is associated with stimulation and emigration of leucocytes, and exudation of lymph and fibrin. It is now well established that the direct bactericidal action of ultra-violet rays destroys surface bacteria and living filter-passing viruses, and although the penetration of the bactericidal rays is small the effects may be sufficient, and the absorption of such irradiated bacteria may increase the local resistance of the tissues, and may also increase general and specific immunity. The absorption of photo-biochemical substances produced by the irradiation of living cells may also add to the increase of the immunity force of the body. In the treatment of disease of the larynx no effort has been made to concentrate ultra-violet rays directly to the lesion, but the rays emitted by the " throat lamp " have been applied to the opening of the larynx as a whole. The reaction which followed has involved, and spread beyond, the irradiated area, and at times has produced the greatest inflammatory changes at the site of the lesion. Healing has continued progressively. It is difficult to decide if the inflammatory reaction produced at the site of the lesion is in itself sufficient to cause this healing, or if the immunity mechanism of the body has been activated locally at the site of irradiation, or if the absorption of irradiated bacteria and irradiated tissue cells by a new vascular field has caused local increase of resistance and stimulation of the immune forces of the body.

OBSERVATIONS ON SELECTED GROUPS OF CASES

Chronic Tuberculous Disease of the Palate and Tongue.—This responded very well to treatment. In all, three cases were treated. In each there was an old history of tuberculous disease of the lungs, but this was well healed and fibrosed before the patients came for treatment. Intensive local treatment was applied to the lesion once every fourteen days, and in one case it was also possible to administer general ultra-violet irradiation twice a week. The dosage of local treatment started with fifteen seconds, and was increased during subsequent treatments to two minutes. Each local application of ultra-violet rays was made by direct contact of the lamp to the site of the lesion. Erythema and oedema followed twenty-four hours later, and spread to the surrounding margins of the ulcer, causing pain and soreness of the tongue and palate. Healing occurred after five or six treatments, giving a smooth, pale scar with little contraction of the mucous membrane. Two of the patients have now been healed for over five years. The third had had previous *x*-ray treatment, and the tuberculous ulcer of the tongue was indurated with hard scar tissue; this increased the resistance of the tissue to ultra-violet rays and delayed healing, and the dosage of ultra-violet rays had to be increased to ten minutes.

Chronic Tuberculous Disease of the Larynx.—Eight cases have been treated, six with successful results—restoration of voice and healing of ulcerated areas. Two patients died, but in these there was intensive involvement of both lungs, and treatment was only applied in an attempt to relieve dysphagia and painful symptoms. In these two cases there was evidence to show that the

local application of ultra-violet rays to the larynx had a sedative and analgesic effect which was of comfort to the patient, for although the reaction following treatment caused erythema and oedema, the oedema appeared to alleviate the painful symptoms for a time, and local anaesthetic spraying and gargles were unnecessary for a short time following treatment

The mucous membrane of the palate, pharynx, and surrounding areas was anaesthetized, and the lamp was inserted beyond the base of the tongue, so that rays of light were directed to the opening of the larynx The upper surface of the lamp was covered with lead foil so as to protect the uvula and soft palate from direct radiation The first treatment was applied for ten to twelve seconds, the patients were made to breathe deeply and slowly while the lamp was applied to the opening of the larynx Reaction of the mucous membrane to ultra violet irradiation was seen twenty four to forty eight hours later, and this caused redness and swelling of the post pharyngeal wall Oedema extended to the soft palate and uvula, although these areas were shaded from direct radiation Laryngoscopic examination showed redness and swelling involving the epiglottis, vocal cords, and arytenoid cartilages The patients complained of soreness of throat, dryness, and pain on swallowing Earache occurred when the irradiation reaction spread to the posterior pillars of the fauces Symptoms subsided three to four days following irradiation and were relieved by gargles, spraying of the throat, local application of infra red and luminous rays, and rest in bed for twenty four to forty eight hours In each of these cases under treatment there was evidence of ulceration, swelling and oedema, and inflammatory granulation tissue of one of the vocal cords, epiglottis, or arytenoid cartilages Healing occurred progressively, with restoration of voice, loss of symptoms, and improved general health

The cases recorded are not sufficient for statistical classification, but the encouraging and successful results should stimulate further clinical research and investigation on larger groups of selected cases

Subacute Glossitis and Ulcers of the Tongue—These lesions are due to chronic inflammatory streptococcal infections, and responded favourably after three to four local applications of ultra violet rays, but the tendency to recurrence was not arrested The lesions were a secondary manifestation of some other primary focus of infection The local treatment checked the pain and caused healing within three to four days, but all the cases I treated had recurrences of ulceration of the tongue and mucosa in other sites several months later Four cases were treated

Chronic Leucoplakia—Although only two cases were treated these have responded well to intensive local application of ultra-violet rays, and have been successfully healed Both were of undiscovered aetiology. Greater trial should be made of this method of treatment in conditions of leucoplakia, for it should prove of help if carried out in conjunction with specific medicinal treatment in cases of syphilitic origin Considerable caution is needed if there is suspicion of early malignant disease, for in such cases ultra-violet radiation is strongly contraindicated, as there is danger that the malignant tissue growth may be accelerated by ultra-violet rays

Chronic Catarrhal Pharyngitis—Forty three cases were treated Successful results have been obtained in obstinate chronic pharyngitis and nasopharyngeal catarrh which have resisted other therapeutic measures—that is, local sprays, medication, vaccines, cauterization, etc Suberythema or mild erythema doses of ultra-violet rays were applied once every week to the pharynx, the nasopharynx, or the tonsillar fossae. Usually three or four local treatments were sufficient to alleviate symptoms of catarrh, cough, or hoarseness of voice Clinically, definite healing of the mucosa was seen, and areas of chronic oedematous inflammatory tissue of the post pharyngeal wall and red eczematous patches of the mucosa of the anterior pillars of the fauces improved, showing a pink and greyish-white smooth area Thickening or scar tissue or contraction of the underlying tissues was rarely observed

Observations on the bacteriology of the mucous membrane before and after radiation therapy were disappointing Before irradiation the cultures taken from the nasopharyngeal, pharyngeal, or tonsillar swabs showed the presence of *Streptococcus haemolyticus* and *Streptococcus viridans*, *Micrococcus catarrhalis*, and Pfeiffer's and Friedlander's bacillus After irradiation the bacteriological cultures grew the same types of organisms It was observed, however, in some cases, that during the erythema stages—that is, twenty-four to forty eight hours after local irradiation—throat and post nasal swabs often grew a pure culture of a haemolytic long chain streptococcus, whereas cultures before irradiation grew a non-haemolytic short chain type of *Streptococcus viridans* These changes in the bacterial flora are difficult to explain, but the original bacterial flora were seen seven days later

Caution is necessary in the dosage of local irradiation in cases of Vincent's angina, and also during the treatment of the "gouty mucous membrane", for severe reaction causing a spreading oedema of the soft palate and uvula may follow, even with mild sub erythema dosage The local irradiation of the pharyngeal and tonsillar mucous membranes may be of great value in the treatment of chronic catarrh following colds, and of chronic infections with streptococci, Vincent's angina, and diphtheria carriers, etc Cases of chronic septic and catarrhal pharyngitis showing clinical signs of redness or oedema of the mucosa, and symptoms of persistent nasopharyngeal catarrh, hoarseness of voice, and troublesome cough, have responded well to radiation therapy after other methods have failed The results of treatment of many of these cases of chronic pharyngitis are similar to the successful results often obtained following the local irradiation of a patch of chronic idiopathic eczema of the skin or of the external auditory meatus The treatment of such lesions with full erythema doses of ultra violet rays will often completely heal a lesion of many years duration in two to three weeks

Conclusion

The cases which I have treated are relatively few, but I hope that observation and the results of the treatment will encourage further clinical research at hospitals and other clinics, where greater access to suitable cases is available

The treatment of the mucous membrane by local radiation therapy must be confined to the specialist The manipulation of the apparatus needs careful and specialized knowledge, and the application and supervision of treatment can only be carried out by fully qualified physicians

I am greatly indebted to Mr Douglas Harmer for his help and kindness During the past two or three years he has contributed some suitable cases for treatment, and checked my observations and results As he says

"In the few cases observed the results obtained by this treatment have been surprisingly good Even a short application of the light for a few seconds only may produce a sharp local reaction, but when applied cautiously the inflammation is never serious or prolonged, and in many instances is followed by rapid improvement Thus in three cases of chronic laryngeal tubercle the lesions healed much more quickly than I should have expected without light treatment Several very obstinate cases of pharyngitis have also improved enormously But the method is comparatively new and therefore requires careful investigation before one can decide which types of inflammation are best treated by it"

ACUTE SCARLATINIFORM DERMATITIS FOLLOWING INJECTION OF TOXOID-ANTITOXIN

BY

GEORGE CHESNEY, M.B., B.CH., D.P.H.

ASSISTANT MEDICAL OFFICER OF HEALTH, POOLE

As I am not aware of any report of a similar reaction following the use of toxoid-antitoxin in diphtheria prophylaxis, the following record of a troublesome allergic dermatitis may be of interest to those engaged in active immunization against diphtheria.

A healthy girl, aged 16, whose work brought her constantly into contact with diphtheritic infection, wished to be immunized. She was Schick-tested on July 14th, 1932, and gave a positive and pseudo reaction. On July 21st a 1 c.cm. dose of toxoid-antitoxin was injected into the region of the deltoid insertion, and next day a reaction about 1½ inches in diameter resulted at the site of inoculation, and she had a feeling of lassitude and malaise. On July 24th a slight itching erythema (somewhat like "prickly heat") appeared on the neck and chest, but its connexion with the injection was not realized. On July 28th a second injection of 1 c.cm. T.A.M. was given, a well-marked local reaction again occurring at the site of inoculation. Two days later the skin erythema flared up in an acute dermatitis, spreading from the neck and chest to the back, the abdomen, then to the arms, legs, and head, until the whole body was involved, with the exception of the hands and feet.

The eruption was bright red in colour, the skin hot, dry, and rather itchy, though not markedly so. Peeling in moderately large flakes began about August 2nd (nine days after the onset), the skin feeling dried up and rendering movement uncomfortable, and in fact painful.

On August 9th, as the condition showed no sign of improvement, and there was marked inflammation of the skin with coarse, flaky desquamation, I sent the patient to see a dermatologist, who regarded the condition as a "sensitization" eruption, arising as an erythema scarlatiniforme.

After about a week's treatment the acute stage of the skin eruption settled down, but the coarse desquamation continued for another week. In view of the disturbance following the injections I decided it would be extremely risky to complete the immunization course by giving the third 1 c.cm. dose of T.A.M. On October 4th I again Schick-tested the patient, the result being pseudo and doubtful positive. Having given several thousand injections of toxoid-antitoxin without any more notable sequelae than in a few cases a localized reaction, and rarely a slight transient constitutional disturbance, I was interested to confirm as far as possible my opinion that the dermatitis was the direct result of the toxoid-antitoxin, and was not purely fortuitous. It was clear that the only positive way by which to confirm the T.A.M. as the exciting cause was to repeat the 1 c.cm. doses, and obviously this course was out of the question. Early in December I again Schick-tested, and, obtaining a pseudo and negative result, I decided to observe carefully the effect of a small dose of T.A.M.; 0.1 c.cm. was given subcutaneously on December 6th, and that evening the temperature rose to 101.1° F., and on the following day the site of the injection was very tender, the surrounding skin red and indurated, and there was general malaise. On December 8th the area was still well defined, about 1½ inches in diameter, the arm being stiff and tender on movement. The morning and evening temperatures were just under 100°. The temperature readings on December 9th were 99.4° (a.m.) and 100° (p.m.), and the reaction was subsiding. On December 10th the temperature remained normal, the patient felt well, and the site of injection was no longer tender or inflamed. In view of the apparent marked intolerance of the patient to the toxoid-antitoxin mixture, I decided to try the effect of a skin test, using a dilution of 1 in 100 of T.A.M. A 0.2 c.cm. intradermal injection was given in the forearm. In twenty-four hours there was a well-defined inflammatory area about 20 mm. in diameter. This persisted for about forty-eight hours, and was somewhat indurated and tender. As I had previously had injections of T.A.M., and was also a pseudo and negative reactor, I injected a similar dose of the dilute T.A.M. intradermally in my forearm as a control, and in twenty-four hours there was a faint flush, without induration or tenderness, which faded by the following day. The result of this test added further confirmation that the patient was very sensitive to even small doses of toxoid-antitoxin. A 0.2 c.cm. intradermal injection of a 1 in 100 dilution of toxoid (M.T.) gave rise in the patient, and in myself as control, to a faint 10 mm. flush, which disappeared within twenty-four hours.

After consultation with Dr. R. A. O'Brien, I carried out skin tests with dilutions of the constituents of the toxoid-antitoxin mixture in an endeavour to ascertain which of the constituents was responsible for the peculiar allergic reaction. On February 28th I made three intradermal tests, using 0.2 c.cm. of a 1 in 100 dilution of the antitoxin serum, 0.2 c.cm. of a 1 in 100 dilution of peptone, and 0.2 c.cm. of a 1 in 100 dilution of veal infusion. That evening there was a well-marked and painful reaction, 5 cm. by 3 cm., at the site of the injection of antitoxin. The following day this area was tender, with a definite palpable raised margin, similar to an urticarial wheal. By March 3rd this reaction was practically gone. There was no reaction to the injections of peptone and veal infusion. Three similar injections in my own case as a control gave rise to no local reaction whatsoever.

REMARKS

There are three methods of explaining the disturbance which commenced toward the end of July: (*a*) that it had no relation to the injection on July 21st or 28th; (*b*) that the patient showed the uncommon type of very acute sensitivity to serum; (*c*) that she was acutely sensitive to the products of metabolism of diphtheria bacillus, which are found in toxoid, and which, in very rare highly sensitive people, may cause unusually troublesome local or general reactions.

The only argument in favour of (*a*) is the extreme rarity of a dermatitis of the kind after the use of the English toxoid-antitoxin mixture or the American toxin-antitoxin mixture. Since the patient in December reacted acutely to 0.1 c.cm. injected subcutaneously, and in February showed an unusual reaction after 0.002 c.cm. of T.A.M. intradermally, it is probable that the dermatitis was due to the injection of T.A.M. In order to find out with certainty which constituent was responsible it would have been necessary to inject subcutaneously, on separate occasions, into the patient, the constituents of the T.A.M., and see whether the fraction of serum, of toxoid, of peptone, or of veal infusion would produce another attack of dermatitis. Although the patient was very helpful, it appeared quite unjustifiable to do an experiment on this scale, and the most that could be done was to carry out the intradermal tests with serum, peptone, and veal infusion in February. All that we can be sure of is that the patient was, at this date, unusually sensitive to serum, and we must rest satisfied with the possible explanation that the minute amount of serum in the original injection of 1 c.cm. of T.A.M. had caused the dermatitis. There was no trace of asthma or any other "allergy" in the previous history of the patient or of her family.

SUMMARY

A troublesome exfoliating dermatitis occurred in a girl of 16, following the injection of two doses of 1 c.cm. of T.A.M. given within a period of seven days. The dermatitis was possibly due to an acute sensitivity to serum.

I am indebted to the patient for her willing co-operation in submitting to the tests, to Dr. S. Watson Smith of Bournemouth for his clinical report on the skin condition, and to Dr. R. A. O'Brien for supplying the test constituents of the T.A.M. and for his valuable critical suggestions.

TREATMENT OF RINGWORM OF THE SCALP WITH THALLIUM ACETATE

BY

DAVID R. LEWIS, M.D., M.R.C.P.

HONORARY PHYSICIAN FOR DISEASES OF THE SKIN TO THE SWANSEA GENERAL HOSPITAL; VISITING PHYSICIAN TO SWANSEA MENTAL HOSPITAL

AND

W. ALFRED LLOYD, L.S.A.

M.O.H. LLANDILO RURAL DISTRICT

The economic situation created by the great war was probably responsible for the rapid development of an easier method of treating ringworm of the scalp in children than the older and more tedious one of *x*-ray therapy.

Since the post-war literature dealing with thallium acetate is so extensive it is unnecessary to give an elaborate account of its history. Soon after its discovery by Crookes[1] in 1861 it was isolated in 1862 in a pure form by Lamy,[2] who recorded its toxic properties. Thallium acetate became fashionable in the field of therapeutics, and was used to control the night sweats of the consumptive, and Combemale[3] (1898) observed that his patients undergoing this treatment lost their scalp hair. In 1898 Sabouraud[4] used thallium acetate for the first time as a depilatory agent in ringworm of the scalp. He used it both locally and internally, and later abandoned it on account of its toxic properties. In 1909 Cicero[5] revived the subject of thallium therapy, and in 1918 published favourable reports on the uses of thallium acetate as a depilatory in ringworm. In the early days of the great war Buschke[6] approached the subject, and has since published periodical reports on the results of his experiments with thallium in rats. In 1922 Buschke and his collaborators administered the drug in the treatment of tinea capitis in children, giving it by the mouth, in a sweetened solution, on an empty stomach. For successful epilation he found it necessary to use a minimum dose of 8 mg. of thallium acetate per kilo of body weight (nude), and further stressed the importance of local treatment during the process of epilation.

In this country Percival[7, 8] has used the drug extensively, and in 1930 published a detailed account of his results of thallium medication in fifty cases of ringworm of the scalp. He maintains that, apart from occasional manifestations of mild toxic symptoms, the patient appears perfectly normal. Recently Ingram[9] has reviewed very lucidly the literature on the subject, particularly in reference to deaths from thallium poisoning, and has come to the conclusion that all the reported deaths have resulted from faulty technique in the administration of the drug. He believes that those who condemn its use as a depilatory agent in ringworm of the scalp do so from a limited acquaintance, and is convinced that, with care, the more the drug is used the less apparent will be the danger. The three deaths recorded by Lynch and Scovell[10] cannot be accepted as a valid objection to its use, for they were, unfortunately, due to an error on the part of the dispenser. Apparently these deaths have created a deep impression on medical opinion in this country, and the drug has gained an evil reputation. The compilers of the new *British Pharmacopoeia* have ignored it entirely. We are still ignorant of its precise mode of action, and until our knowledge has increased we cannot lay down a hard-and-fast rule for its administration. Recently Vasarhelyi[11] and Buschke have published their investigations on the changes in the skin produced by thallium. They conclude that a local application of it can cause alopecia, and also slight inflammatory changes, and that the drug absorbed from the skin causes general thallium phenomena. Thanks to the patient work of Cicero and Buschke, the experimental stage has been successfully passed, and it is evident that thallium acetate is being used more and more in the treatment of tinea capitis in children. Our knowledge of its elimination and rate of absorption is only partial, and although we have certain facts to guide us in its administration, our ignorance of its pharmacological action still awaits daylight.

Sabouraud regarded such toxic manifestations as tachycardia, cutaneous erythemata, and subcutaneous haemorrhages to be the result of impurities in the preparation he used. Other early observers maintained that the lead contained in thallium was responsible for the toxic properties of the drug. Its toxic manifestations undoubtedly simulate those of lead to a marked degree. Like lead, it is a protoplasmic poison, and a comparison of the symptomatology is interesting. Both have a predilection for nervous tissue and are cumulative in action. The cramp-like abdominal pains, peripheral neuritis, and blurred vision of lead poisoning are frequently observed in thallium poisoning. The blue line so characteristic of lead absorption has also been observed in thallium poisoning. Adler[12] refers to the changes in the finger-nails observed as a late symptom of it. About the eighth week after administration he noticed in one of his cases a white horizontal band on each finger-nail and equally distant from the base of the nail. He mentions that this band could easily be distinguished from the white zones which are often observed in some other diseases. His observation is of interest in comparing the two elements, for one of us (D. R. L.) has observed similar bands to those described by Adler on the finger-nails in a case of lead poisoning. A few of the early writers found stippling of the red blood corpuscles in thallium poisoning, but latterly Testoni[13] and other observers have failed to demonstrate stippling in their cases. The analogy between thallium poisoning and lead absorption is interesting, for it is a well-known fact that a moderate amount of lead in the system, although toxic, is not apparently harmful, and does not shorten life.

The fact that thallium is a protoplasmic poison must not be overlooked, and its administration must be carried out with care and vigilance, for it is certainly well known that the difference between the maximum therapeutic dose and the toxic dose is very small. Lynch and Scovell have objected to its use on the grounds that it might do permanent damage to the growing organism, but Percival and Ingram have found no such evidence in their extensive experience of the drug. They believe that the mild toxic manifestations observed after the proper administration of the drug are a passing phase, and of no significance.

RESULTS IN FIFTY CASES

Our report is of fifty cases of small-spored ringworm of the scalp which were treated by the oral administration of thallium acetate. Twenty of the treated children were inmates of an orphanage home in Carmarthenshire, and were under the medical supervision of one of us (W.A.Ll.). The opportunity of daily observation was valuable from the point of view of gaining first-hand information of the toxic manifestations or any other psychical disturbances. One of the children was an epileptic, and another had a spinal curvature. The ages of the children treated ranged from 4 to 12.

A routine medical examination was carried out, and particular attention was paid to the examination of the urine. The child was then weighed nude, and the weight recorded. With two exceptions every child was given by the mouth a single dose of a sweetened solution of 8.5 mg. of thallium acetate per kilo of body weight. We hesitated in giving the usual therapeutic dose in the cases of the kyphotic and the epileptic child. In the former a middle course was adopted, and we gave the child 5 mg. of thallium acetate per kilo of body weight, and a half-pastille dose of *x* rays immediately after the administration of the drug. The Kienbock-Adamson method was used in giving the *x* rays, and a half-pastille dose was given to the different areas instead of the full pastille dose. The epileptic child was given 7.5 mg. of thallium acetate per kilo of body weight. The parent or guardian was then advised to cut the hair short, if not already cut, and ordered to apply a 2 per cent. solution of iodine thrice daily

to the scalp for another four weeks. The patient was advised not to wash the scalp for the first fortnight. At the beginning of the third week the scalp was washed with soap-and-water. This is the method recommended by Ingram, and it proved a very satisfactory one, though not superior to the vigorous local application of a 10 per cent. sulphur ointment recommended by Percival. In three cases we found that even a 2 per cent. solution of iodine proved too irritating to the children, and a 10 per cent. ung. sulphuris application was applied daily for three weeks instead.

The scalp was epilated in every case except two, and in the latter the full therapeutic dose was not prescribed on account of their state of health. One of our failures was an epileptic, and the other had a spinal curvature. In the former, the drug produced no ill effects, and has not increased the frequency of the fits. Falling of the hair was first noticed on the twenty-fifth day, and the scalp was never completely bald.

In the child with a spinal curvature epilation was never complete, and for many weeks after the administration of the drug and *x* rays the bald irregular patches on the scalp presented a curious appearance. On the fifth day following the administration of the drug a scarlatiniform rash was noticed on the child's neck and face. On the eighth day the rash had disappeared, and the child complained of itchiness of the skin and pain under the heels. The child was somewhat lethargic for a few days. A rash was observed in three children.

Toxic symptoms were observed in 43 per cent. of our cases, and, with the exception of one child, were of a mild pseudo-rheumatic character. The commonest symptoms were malaise, lethargy, weakness, and loss of muscular power and pains, particularly in the legs. The lower limbs seemed to be most commonly affected.

One case only in the series gave rise to anxiety. He was a boy of 5, and on the eighth day a diffuse rash was noticed on his legs. On the eleventh day the rash appeared all over his body. The face and neck were swollen, and the legs were oedematous. The temperature was normal, and a trace of albumin was found in the urine. The child remained in bed for a week, and made an uneventful recovery. He weighed 15.9 kilos, and 15.9 c.cm. of a solution containing 8.5 mg. of thallium acetate per c.cm. was administered.

CONCLUSIONS AND SUMMARY

It is claimed that older children are more liable to show toxic manifestations. We found that no particular age period was exempt, and only a few of the children exhibiting toxic manifestations were confined to bed. They all made a complete recovery. All the children, except two, responded well to treatment, and fulfilled the usual tests for a cure. *X* rays and thallium acetate administration are the only two satisfactory methods known for treating ringworm of the scalp. Both have their firm adherents. *X* rays have proved their value, and the expert has produced perfect results. It must be borne in mind, however, that in less experienced hands they cannot be used without danger, and many partially bald heads still linger as a monument to faulty *x*-ray therapy in early infancy. The superiority of thallium acetate treatment over *x* rays is most obvious when an epidemic of ringworm of the scalp has to be combated. In the treatment of the twenty children from the Cottage Homes we were able to stamp out the disease, with the aid of this drug, in eighty-five days. With *x* rays it would have taken us a much longer time, and it would have also entailed much more labour. According to Percival, the average duration of treatment at Edinburgh, from the time of administration of the *x* rays till the cure of the disease, was 135 days. It is impossible in the average skin clinic in the course of an epidemic of ringworm to treat every case immediately by *x* rays, whereas thallium acetate can be given at once to every child as soon as the diagnosis is made. The children at the institution have been carefully watched (by W. A. Ll.) for six months, and nothing unusual has been noticed in their physical or mental development. Although the new method may prove a snare to the unwary and has been severely criticized, our results have been particularly satisfactory. The children are healthy, vigorous, and mentally alert.

To summarize. Thallium acetate is a dangerous drug, and therefore requires careful technique in its administration. Like lead it is a cumulative poison, and must not be repeated for at least four months. Toxic symptoms are rarely severe, and even the severe case encountered in our series recovered without any sequelae. When properly administered it can be used with ease and safety in the treatment of ringworm of the scalp.

THE POSTERIOR FOSSA COMPRESSION SYNDROME

BY

LAMBERT ROGERS, M.Sc., F.R.C.S.

ASSISTANT DIRECTOR OF THE SURGICAL UNIT, THE WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF

Having several times in the course of the past twelve years encountered a syndrome which, although it may occur from high generalized intracranial tension, appears to be particularly characteristic of rapidly increased intracranial pressure in the posterior cranial fossa below the tentorium cerebelli, I venture to draw attention to it in the hope that its more general recognition may lead to its effective treatment. If ineffectively treated the condition is fatal. The first case of which I had experience (when a house-surgeon) was due to a fracture of the base of the skull and ended fatally; others with a similar termination have also been related to me. Since recognizing the syndrome and its cause, I have been privileged to tide a patient through it.

THE SYNDROME

The patient collapses and respiration stops, while the heart continues to beat vigorously. If nothing is done the heart soon ceases to beat, the patient previously becoming more and more cyanosed. A failure of the respiratory centre evidently takes place; the cardiac centre being apparently less vulnerable to the effects of sudden compression, the heart action continues. Artificial respiration results in the diminution of the cyanosis, and patients have been kept alive for ten or twelve hours while artificial respiration has been kept up; but as soon as this has flagged the cyanosis has increased, the heart has slowed, and, when artificial respiration has finally ceased, the patient has died. Such a case was reported to me by Professor Sheen as having been met with in his

experience, and one occurring in my own experience and produced by haemorrhage from a fracture of the base of the skull running through the posterior fossa has already been mentioned

The cause of the syndrome would appear to be the relative vulnerability to pressure of the respiratory as compared with the cardio inhibitory centre The compression may be produced by haemorrhage into the posterior fossa or by an intracranial tumour or abscess, and in the latter instances may result from oedema in association with the lesion This was apparently the mechanism in the case which follows Recognition of the syndrome enabled one to relieve the condition and subsequently deal with its cause, a cerebellar cystic glioma

HISTORY OF CASE

The patient, a single woman aged 30, was transferred to the surgical unit from another hospital with a diagnosis of cerebellar tumour The signs and symptoms were typical of such a lesion, and there was a high degree of bilateral papilloedema A ventricular estimation had been carried out, and she was in one of the unit wards awaiting operation when one morning I had an urgent message from the house surgeon (Mr J F Meredith), asking me if I would come and see her as she had suddenly collapsed On reaching the ward I found him carrying out artificial respiration The patient was unconscious, and as soon as the efforts at artificial respiration were relaxed she would become cyanosed, the pulse would slow and eventually stop, and she would be to all appearances dead, but with renewed artificial respiration the pulse would come back, the cyanosis pass off, and her colour improve

With a knowledge of the outlook—namely, indefinitely prolonged artificial respiration and then death when exhaustion of the workers led to cessation of artificial respiration—it was realized that radical action was imperative An oxygen cylinder and a gum elastic catheter were sent for By manipulation the catheter was placed through the glottis on connecting it to the oxygen supply the colour of the patient was kept pink and the pulse remained good She was taken at once to a theatre, and without any anaesthetic and with the assistance of my colleague Mr R V Cooke and of Mr Meredith a suboccipital decompression consisting of the removal of the greater part of the post occipital bone back to the foramen magnum so as to remove its posterior margin, and a laminectomy of the atlas, were carried out When the dura mater was opened the cerebellar tonsils bulged into the wound and the medullary compression was evidently relieved At this stage respiratory movements commenced, shortly afterwards the oxygen supply was turned off, and it was found that the catheter could be withdrawn from the trachea The wound was closed and the patient returned to bed She regained consciousness and recovered from her alarming experience with no untoward effects except for a small cerebrospinal fluid fistula, which, however soon closed The decompression relieved her symptoms to a great extent, and she was discharged to her home and was comparatively well for eight months She was then readmitted and the cyst removed from the cerebellum but unfortunately she contracted bronchopneumonia from which sixteen days after operation she died The interest in the case here however lies in the appearance of the posterior fossa compression syndrome and its treatment by emergency posterior fossa decompression

COMMENT

By prompt radical treatment it may be possible to tide the sufferer from its effects through an otherwise fatal syndrome, and it would appear that, when in a case of raised intracranial tension—whether from haemorrhage, new growth, or abscess—respiratory failure occurs, prolonged efforts at artificial respiration should not be carried out, but with all possible dispatch relief of medullary compression should be secured by an emergency posterior fossa decompression Oxygen administered through an intratracheal catheter, as in this case, may enable the operation to be undertaken, but, failing introduction of a catheter in this way, an emergency tracheotomy or laryngotomy would appear to be advisable and the oxygen should be supplied by this route It might be objected that, rather than the performance of such a radical procedure, a reduction of intracranial tension with relief of medullary compression might be brought about by ventricular tap or by intravenously administered hypertonic salt solution or glucose, but such means would appear less certain, and in any case would produce only transitory effects In the posterior fossa compression syndrome, therefore, the indication would appear to be an extensive mechanical relief of pressure, as in the case to which reference has been made.

A CASE OF MALARIA DUE TO PLASMODIUM OVALE STEPHENS 1922

BY

N HAMILTON FAIRLEY, M D, F R C P

LECTURER IN CLINICAL MEDICINE AND APPLIED PATHOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

Stephens (1922) reported a new malaria parasite in a man coming from East Africa, and named it *Plasmodium ovale* on the basis of its morphological features in the asexual stage, pointing out that it resembled rather closely the quartan parasite, but that infected corpuscles were frequently oval in shape and showed Schuffner's dots Later, Stephens and Owen (1927) described another instance of infection with *P ovale* in a case from Nigeria, male and female gametocytes were on this occasion described which were indistinguishable from those of quartan except for the stippled, decolorized margin of the red cell, they concluded that the relationship, if any, of *P ovale* to *P malariae* remained to be demonstrated

Warrington Yorke and Owen (1930) met with an infection with *P ovale* in a hospital patient from Nigeria, and by means of direct blood inoculation passed it through a series of five general paralytics or tabetics The parasites were morphologically indistinguishable from *P malariae*, but the cycle of schizogony was completed in forty eight hours, and the temperature charts were tertian in type The infected red cells were moderately enlarged, and occasionally enormously so, they were pale, fragile, frequently oval in shape, having usually an irregular, raggy outline, and being heavily stippled, as described by Stephens

James, Nicol, and Shute (1932) obtained blood containing *P ovale* from a case of Professor Warrington Yorke's, passaged it through fourteen general paralytics, and studied the sexual form in the mosquito, the arrangement of pigment in young oocysts was found distinctive The disease was also transmitted by the bite of experimentally infected mosquitos, *Anopheles maculipennis* as well as by sporozoites obtained from the salivary glands and injected intravenously Later the same authors (1933) reviewed the whole subject, and concluded that the nomenclature of *P ovale* was correct

Since 1922 only four naturally infected cases appear to have been diagnosed in this country, and for this reason the following case, which presents several features of interest, seems worth recording

CASE RECORD

The patient, a male aged 28 years was sent by his firm on August 8th 1932, for examination regarding his suitability for the Tropics, and following a favourable report proceeded to West Africa, arriving at Lagos on September 19th 1932 and leaving Freetown on February 9th 1933 for England During this period of 143 days he visited Nigeria the Gold Coast, Gambia and Sierra Leone in this order and was quite well except at the end of October in Lagos when he was severely bitten by sand flies and suffered from an attack of

LIBRARY

fever lasting two days. Throughout the tour he used mosquito boots, a mosquito net at night, and took quinine (five grains daily) as a prophylactic measure. At no time was he conscious of being bitten by mosquitos.

The patient arrived in England on February 20th, 1933, and was quite fit until March 22nd, when at about 7.30 p.m. he developed a rigor lasting half an hour; this he attributed to a chill. The second attack came three days later—that is, March 25th—when a rigor occurred at 7.20 p.m. and lasted one and a half hours. The third attack occurred on March 27th, about 6.30 p.m., and by 8 p.m. the temperature had risen to 103.8° F.; on this occasion the rigor lasted two hours, and the patient sweated freely after taking hot drinks. The fourth attack, on March 29th, came on at 6.30 p.m., with a rigor lasting three-quarters of an hour; by 7 p.m. the temperature was 101°, and again profuse sweating occurred. On each occasion the patient said the rigors were of a mild character, and that the shivering could to some extent be voluntarily controlled.

On March 30th the patient was referred to me by Dr. R. H. Dixon with suspected malaria. Examination then revealed a palpable spleen, a temperature of 98.8°, a yellow skin, and a dark-brown urine, which showed urobilin (+) and a trace of bile salts and albumin. The leucocyte count was 7,200 per c.mm.; the differential count showed neutrophils 58 per cent., lymphocytes 30 per cent., monocytes 11 per cent., eosinophils 1 per cent. In blood films prepared with Leishman's stain the laboratory reported that malarial parasites, atypical in type and resembling quartan malaria, were present. Owing to the fact that the temperature, though originally quartan, now showed a tertian type of periodicity, infection with *P. ovale* was suspected on clinical grounds, and this was confirmed by Dr. C. M. Wenyon, who re-examined the blood films. Dr. Wenyon reported that the morphological appearances of the parasite were typical of *P. ovale*, that the characteristic distortion of the red cells was present, and that the infected corpuscles were heavily stippled with Schüffner's dots in films stained overnight with Giemsa, though they were not evident in Leishman-stained films.

Next day (March 31st) the patient was admitted to the Hospital for Tropical Diseases. The temperature reached 99.4° at 6 p.m., and blood films again revealed *P. ovale*. The red blood cells were 4,720,000 per c.mm.; haemoglobin 90 per cent.; colour index 0.96; diameter 7.2 μ. The urine showed bile salts (+), urobilin (+), and a trace of bile pigment, while the van den Bergh reaction gave a negative direct but a strongly positive indirect reaction of 2.5 units. Oxalated plasma collected under paraffin showed no trace of oxyhaemoglobin bands when examined spectroscopically through a thickness of 1.3 cm. The plasma urea was 38 mg. per cent., and the plasma cholesterol 109 mg. per cent. Treatment was commenced with atebrin, 0.1 gram being given per os. Next day (April 1st) there was malaise, the temperature reached 100°, but there was no rigor. Atebrin was continued, 0.1 gram three times daily, and quinine bihydrochloride, 7½ grains in 10 c.cm. of saline, was injected intravenously.

The subsequent clinical course was afebrile and uneventful, and parasites permanently disappeared from the blood. Intravenous injections of quinine (7½ grains) were continued daily until April 4th, and atebrin (0.1 gram three times daily) until April 5th. The urine had by then lost its dark-brown appearance, and though bile salts persisted only a trace of urobilin was detected; the van den Bergh reaction was also found to be normal—indirect reaction 0.2 unit. The reticulocytes equalled 3.6 per cent., and from this date until April 8th the daily reticulocyte counts were 5.7, 6.3, and 3.4 per cent. respectively. On April 10th the reticulocytes had fallen to 2.5 per cent.; red blood cells, 5,120,000 per c.mm.; haemoglobin, 102 per cent.; colour index, 1.0; average corpuscular diameter, 7.2 μ; leucocytes, 8,300 per c.mm.; the differential count was normal, the monocytes having fallen from 11 to 3 per cent. By April 11th the reticulocytes had reached a normal level—that is, 1 per cent.; the urine was also normal, the spleen was no longer palpable, and the patient was discharged from hospital.

When seen again, on April 22nd, clinical examination revealed no abnormality, the blood showed no evidence of parasites, the van den Bergh reaction was normal, and the urine contained neither urobilin nor bile salts.

COMMENTARY

This case is an instance of infection with the fourth species of malaria parasite—that is, *P. ovale* Stephens 1922—contracted during a short tour of 143 days in West Africa. Throughout this period the patient had consistently taken prophylactic quinine, and this is the probable reason for the long incubation period, unless the two days' fever in Lagos be interpreted as representing the primary malarial attack.

The species of parasite was suspected on clinical grounds when the laboratory reported atypical quartan malaria in a febrile patient who, though at onset manifesting quartan, later showed a tertian periodicity. Another peculiar feature was the late time of onset of the rigors, which occurred between 6.30 and 7.30 p.m.; generally malaria fever commences before or about midday, as emphasized by Manson.

The biochemical and haematological observations were of interest. Haemoglobinaemia was not evident at the time the plasma was examined, but the urobilinuria and hyperbilirubinaemia indicated that the blood destruction usually associated with malarial fever was going on. Bile pigments in the urine are unusual in malarial fever, and probably originated from a mild toxic hepatitis in this instance. The reticulocytosis reached a maximum of 6.3 per cent. some eight days after the initiation of specific treatment. This is usual in malaria, for once the parasites are controlled or destroyed regenerative activity of the bone marrow results in reticulocytosis and new blood formation.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

RECURRENT RENAL CALCULI

NEPHROLITHOTOMY TWICE ON EACH KIDNEY IN THE SAME PATIENT

Mrs. X, then aged 37 years, was sent to me in February, 1911, by the late Dr. Sortain Hancock, with definite signs and symptoms of stone in her *right* kidney. Radiographic examination proved the presence of a large branched calculus occupying the pelvis and some of the calyces of that organ.

I performed nephrolithotomy on February 15th, and removed, as I thought whole, a large stone with four "legs." The wound was drained for the first forty-eight hours, and then healed rapidly, and she was discharged on February 25th, ten days after the operation. There was no evidence then of any calculus in her left kidney.

She was readmitted on April 25th, 1914, now with definite evidence of a stone again in her *right* kidney, and one also in her *left* kidney. On May 1st, 1914, I explored her *left* kidney, the one which had not previously been exposed, and removed a stone. The wound healed rapidly. On May 19th, 1914, I explored her *right* kidney, the one from which I had removed the large stone in 1911, and found and removed a small stone from the pelvis. This may have formed upon some debris which I had failed to extract at the first operation.

Two years later, in March, 1916, she again showed herself with evidence of stone, once more in her *left* kidney. By this time she had become an "expert" in the diagnosis of renal calculi, and she ventured to bring her brother, in whom she was sure there was a stone in his *left* kidney! And so it turned out to be. I admitted them both to the hospital on the same day, I operated on

the *left* kidney of each on the same day, the sutures were removed from each on the same day, they got up in the ward on the same day, and together they left the hospital with soundly healed wounds on the same day, eighteen days after the removal of their calculi.

Thus it will be seen that the woman is probably a unique person, having had both of her kidneys dealt with twice over. I may add that she has never had a further recurrence, and is alive and active to-day at the age of 60 years.

W. MCADAM ECCLES, M.S., F.R.C.S.,
Consulting Surgeon to St. Bartholomew's Hospital.

ENCEPHALITIS FOLLOWING VACCINATION: WITH RECOVERY

The number of cases of post-vaccinal encephalitis recorded in this country is small. For this reason, and in view of the striking recovery, the following case appears worthy of record.

A well-developed girl of 17 was admitted under my care at the Royal Devon and Exeter Hospital on April 25th, in a stuporous condition. Fifteen days previously, while in her usual state of sound health, she had been vaccinated with Government lymph by a single insertion on the outer side of the thigh. She had never before been vaccinated. The vaccination took well, and was followed by a mild febrile reaction at the end of a week, necessitating three days in bed. On the morning of the fourteenth day she felt unwell, but did her work. That evening Dr. H. Temkin was sent for; he found her cheerful and presenting no signs other than a temperature of 103° F. and general aching. She was "noisy" that night, and was found to be stuporous when seen the next afternoon by Dr. Temkin, who sent her forthwith into hospital.

On admission she was semi-comatose, screaming, resistive, photophobic, and made no response to simple requests. Temperature was 99.6°, and pulse 68. The pupils were small, but were reacting to light, the optic fundi were normal. No cranial nerve paresis was detected; but the neck was stiff. Abdominal reflexes were absent. Biceps, triceps, and knee-jerks were very sluggish, and the ankle-jerk was obtainable only on the left side; plantar reflexes flexor. Kernig's sign was not present. Catheterization of the bladder was necessary, and an enema was retained. No feeding by the mouth was possible, except by a tube. Heart, lungs, and urine were normal. Lumbar puncture was performed that evening and again next morning (when coma had become complete), with no relief of symptoms. The cerebro-spinal fluid was under pressure, turbid, and of greenish colour, and was reported on by Dr. W. A. Robb as follows: red blood cells, 753 per c.mm.; leucocytes, 118 per c.mm., of which 82 per cent. were lymphocytes and 18 per cent. polymorphonuclears; protein, 90 mg. per 100 c.cm; globulin (Nonne-Apelt reaction) positive; glucose, 50 mg. per 100 c.cm.; chlorides, 670 mg per 100 c.cm; no organisms seen by Gram film; no tubercle bacilli found; culture sterile.

At 5 30 p.m. that day (April 26th) a third lumbar puncture was performed, when, after escape of fluid, 30 c.cm of blood serum from a nurse successfully vaccinated three and a half months previously was slowly injected into the theca. One and a half hours later I observed the patient begin to talk semi-incoherently, but for the first time since admission. By the next morning she was rational, though excited and dazed; but another similar injection of the serum was made into the theca. Temperature was normal and remained so. On the fifth day after admission (April 30th) she appeared to have recovered completely, except for control of the bladder, which she did not regain until May 2nd. On that date the tendon jerks were all normal; the abdominal reflexes, however, still remained absent at the beginning of June. Well-marked desquamation commenced at the end of the second week in hospital. On May 8th a second examination of the cerebro-spinal fluid by Dr. Robb showed: 14 leucocytes per c.mm., all lymphocytes; 4 red blood cells per c.mm.; protein 35 mg. per 100 c.cm.; globulin test negative; glucose, 70 mg. per 100 c.cm.; chlorides, 705 mg. per 100 c.cm.

Among the points of special interest in this case are: (1) the incidence in adolescence and in a person previously unvaccinated, as in the vast majority of cases reported in the literature; (2) the vaccination was by the single insertion now recommended; (3) the mild lymphocytic reaction as typically found in human encephalitis following vaccination,[1] and as also mentioned by Mackintosh and Scarff[2] and others in experimental researches; (4) the dramatic recovery immediately following intrathecal introduction of an immune serum; it appears that a smaller and single dose of the serum used would have fulfilled the needs of this case, as in that described by Lord Horder,[3] where a single introduction of 5 c.cm was successful.

I wish to acknowledge my great indebtedness to Dr W A Robb for his examinations of the cerebro-spinal fluid and preparation of the serum.

SPINAL ANAESTHESIA IN AN INFANT

In the recent articles published in this country on spinal anaesthesia so little has been mentioned of its use in children and infants that I consider an account of the following case of some interest.

A male child, aged 27 weeks, was admitted to the Bolton Royal Infirmary on November 25th, 1932, with a history of intermittent screaming, apparent abdominal pain, and the passing of "red currant jelly" material per rectum. The screaming had commenced three hours before admission. The temperature was 103° F., pulse 128, and respiration 30. A mass was palpable in the left iliac fossa; rectal examination revealed only blood-stained material on the examining finger.

Operation under spinal anaesthesia was decided upon, and a small area of skin between the third and fourth lumbar vertebrae was anaesthetized with 1 per cent. novocain. Lumbar puncture was performed through this, and 3 5 mm. of 5 per cent. stovaine and glucose solution, mixed with an approximately equal quantity of cerebro-spinal fluid, was injected intrathecally. The child was then placed in a 10 degrees Trendelenburg position, which was maintained throughout the subsequent operation. At the end of four minutes anaesthesia was complete up to the nipple line. The abdomen was then opened, and an intussusception of the ileo-colic type, with the apex reaching almost to the brim of the pelvis on the left side, was found. This I reduced with ease. The abdomen was then closed. During the operation the child appeared much less distressed than previously, and during the suture of the wound he slept apparently undisturbed.

The anaesthesia was much more satisfactory than that usually obtained with a general anaesthetic in similar cases, and the child seemed to suffer the minimum of discomfort from the moment it took effect. This was most marked in the hours immediately following operation, when the child slept naturally and soundly. The subsequent convalescence was rapid and uneventful, the child taking the breast soon after the operation, at no time was artificial feeding employed. The child was discharged from hospital on the tenth day, and has since made an uninterrupted recovery.

IAN D KITCHIN,
Resident Surgical Officer, Bolton Royal Infirmary

Reports of Societies

OXFORD OPHTHALMOLOGICAL CONGRESS

The twenty-third annual meeting of the above congress was held at Oxford on July 5th, 6th, 7th, and 8th. Members met informally at dinner on the 5th in the Hall of Keble College, which had, as in former years, again offered its hospitality. The proceedings of the congress were held in the Department of Human Anatomy of the University, kindly lent for the purpose by Professor Arthur Thomson, to whom the congress is under a deep debt of gratitude. In addition to the scientific museum, a commercial exhibition was on view, in which numerous well-known firms of ophthalmic instrument makers displayed the latest forms of apparatus and instruments used in ophthalmic surgery. As usual, a large number of foreign members and others resident abroad attended the congress, which emphasized once more the international character of this meeting. Among the visitors were Dr. Holth of Oslo, Dr. Uribe Troncoso of New York, Dr. Bernard Samuels of New York, Dr. Holm of Copenhagen, Dr. Van Heuven of Utrecht, Dr. Rau of Bangalore City, Dr. Van Poole of Honolulu, Dr. Pearson of China, Dr. Sohan Singh of Amritzar, and Dr. Meyer of South Africa.

PROCEEDINGS

The proceedings began on Thursday, July 6th, with a short address of welcome from the Master, Mr. CYRIL WALKER. Immediately following, Dr. S. HOLTH of Oslo opened a symposium on "The Treatment of Glaucoma, excluding Operative Details."

Dr. Holth described his speech as "historical remarks on the treatment of primary glaucoma." He fully described iridectomies before and after local anaesthesia with cocaine in 1884, and discussed the treatment by miotics since 1876. Next he dealt with anterior sclerectomies from the time of their introduction in 1904. An account was given of the tonometer, which was introduced in 1905, and with it the early treatment of chronic glaucoma. Dr. Holth then proceeded to a comprehensive discussion on "filtering scars" and the various methods by which they can be obtained.

Colonel ROBERT WRIGHT continued the discussion, citing freely from his large experience in Madras. He first discussed the non-congested type with markedly high tension, advanced field changes, and diminished visual acuity. He described the preliminary treatment to reduce tension so that operation could be performed under the best conditions, and emphasized the advantage of the adrenaline pack, together with the frequent use of eserine and massage. If the tension did not fall he preferred to perform an anterior sclerotomy, watching the effect on the iris vessel with operating lenses. He also favoured cyclodialysis, which had given astonishingly good results. In a second group of cases in which the symptoms were not so marked, careful field-taking, tonometric observations, and watching the effect of non-operative measures were recommended. The operation of iridencleisis was warmly commended, but it was felt necessary in these cases to keep in touch with the patient for some little time afterwards. Colonel Wright discussed the question of operation in mild or early cases, where the tension was only raised a trifle, and that occasionally. The treatment of acute congestive primary glaucoma was then gone into in detail, and the intravenous injection of hypertonic solution of sodium chloride was praised. Acute secondary glaucoma and its treatment was also dealt with. The discussion was continued by Dr. GEORGE YOUNG and Dr. BURDON-COOPER, who dealt with the non-operative treatment of glaucoma.

Dr. URIBE TRONCOSO of New York then gave a most interesting paper on clinical gonioscopy, introducing details as to the use of the gonioscope and the findings in normal eyes. In the second part of his remarks he described minutely the clinical appearances as seen with his instrument after operations for glaucoma. In the afternoon Dr. DOROTHY CAMPBELL gave a highly technical paper on the chemical pathology of cataract, which was followed by another on the same subject by Dr. BURDON-COOPER. Mr. H. J. TAGGART then read a well-illustrated paper on the treatment of ptosis by a modification of the Motais operation. Mr. ZORAB related a successful case which had been operated upon by this method. In the afternoon the members of the congress and their friends had tea at Wadham College, being received by the Warden and Mrs. Stenning, and were shown the beautiful gardens.

The annual dinner of the congress, at which 108 members and their friends sat down, was held the same evening, presided over by Mr. Cyril Walker, the Master.

MEMORIAL LECTURE AND OTHER PAPERS

On July 7th Dr. STOBIE, physician to the Oxford Eye Hospital, gave an interesting address on the constitutional factor in diseases of the eye. Passing from the subject of errors of refraction and the state of health, he discussed the factors in phlyctenular conjunctivitis—infection or diet. The role of tuberculous infection in iridocyclitis was also described. The speaker then dealt with the difficulty of obtaining negative blood tests in the treatment of interstitial keratitis, and the early ocular symptoms of disseminated sclerosis. Next he attempted to correlate the general picture of hyperpiesis, arterial sclerosis, and renal disease with retinal findings, and made some observations on treatment.

The Doyne Memorial Lecture was given by Mr. BERNARD CRIDLAND, the subject being "Investigations on the Aftermath of Cases of Intraocular Foreign Bodies." This lecture does not lend itself to abstraction, and should be read in the original. It embodied case records of intraocular foreign bodies which had remained in position for five years and over. At the conclusion the Master, after complimenting the lecturer, presented him with the Doyne medal.

Dr. R. S. CREED then gave a highly technical address on ocular after-images, presenting most interesting details of his experiments in these phenomena. This paper was discussed by Mr. CYRIL WALKER, Dr. YOUNG, and Mr. HARRISON BUTLER.

In the afternoon a discussion on diathermy in ophthalmology was opened by Mr. FRANK LAW of London, who described in some detail the technical side, and the clinical results obtained in various diseases—notably, glaucoma and corneal affections. He was followed by Mr. AFFLECK GREEVES, with an account of Safar's operation for detached retina. Mr. F. A. ANDERSON gave a highly technical paper on the localization of intraocular foreign bodies by the method of Professor Dr. Guido Holzknecht, describing his own modifications of this method. Dr. ROSA FORD read a paper on recovery from strabismus amblyopia after twenty-nine years by continuous drainage of the nasal accessory sinuses. On Saturday morning Dr. BERNARD SAMUELS of New York gave a very exhaustive paper on a study of eighty-five cases of necrotic sarcoma of the uvea. He pointed out that in gliomata necrosis took place early, whereas in sarcomata the toxic effect was much more marked. The paper was discussed by Mr. HARRISON BUTLER and Colonel WRIGHT. Mr. ALABASTER and Mr. STIRK ADAMS then gave, in a preliminary communication, the results of an inquiry into the conditions of the ears in miners' nystagmus.

This concluded the proceedings of the congress, which all agreed had been a most successful one. The Master stated in his closing remarks that 121 members had attended.

VENEREAL DISEASES

The sixth Imperial Social Hygiene Congress, organized by the British Social Hygiene Council, was held at the London School of Hygiene and Tropical Medicine from July 3rd to 7th, under the general presidency of Sir Basil Blackett. Reports were made and discussions took place on imperial health services, social education, the outlook on prostitution, and the teaching of biology. Two medical sessions were held, one of them dealing with problems in the treatment of acute gonorrhoea, and the other with administrative measures in connexion with venereal disease.

TREATMENT OF ACUTE GONORRHOEA

Mr. DAVID LEES (Edinburgh), in the course of some observations on the prevention of complications in acute gonorrhoea, especially in the male, said that there was no doubt that the course of a gonococcal infection could be cut short and many of the complications which followed on an established urethritis obviated if infected persons could only be educated to seek medical advice as soon as they felt the slightest discomfort in the urethra subsequent to having taken the risk of infection. In established gonorrhoea of more than twenty-four hours' duration the prevention of complications called for co-operation between the patient and his medical attendant. Avoidance of physical overstrain, complete abstinence from alcohol in any shape or form, and the avoidance of sexual excitement or excess were essential. He emphasized the importance of avoiding instrumental interference with the urethra until all acute symptoms had subsided completely, and spoke of the value of prostatic and vesicular massage in the declining stages of all cases, especially in those of posterior urethritis. On the subject of adjuvant methods of treatment Mr. Lees said that he had found uncomplicated cases of gonorrhoea in both sexes, especially those seen in the earlier stages, derive marked benefit from the administration of an appropriate vaccine. He favoured a detoxicated vaccine in that it might be given in moderately large doses without producing any severe reaction. When the urethral symptoms were very acute, and in complications such as prostatitis, vesiculitis, and prostatic abscess, he had been more successful in alleviating the acute manifestations of the disease and in preventing further complications by giving a protein. Serum treatment or passive immunity had not in his experience proved successful in gonorrhoea.

Dr. GLADYS SANDES (London Lock Hospital), in dealing with the prevention of complications in the female, said that the first essential in treatment was to establish an accurate diagnosis, and this should be done primarily by clinical observation and confirmed by pathological examination by a skilled pathologist. By the trained observer acute gonorrhoea could nearly always be diagnosed clinically. When such diagnosis was the probable one, it was much better to do too little than too much. It was quite time enough to begin active local treatment when the disease had become subacute. As for complications, these could not always be avoided even in the most skilled hands. Urethral massage and a careful search for infected Skene's ducts reduced the likelihood of the formation of a suburethral abscess, but to prevent the development of Bartholin's abscess was more difficult.

Dr. EDWARD L. KEYES (president, American Social Hygiene Association) spoke somewhat sceptically of antiseptics, which, he said, were commonly used in such dilutions as to diminish greatly any value they might possess. The drugs which did well were of the class which he was inclined to call, for want of a better word, astringents. It was not so much the claim that local remedies had antiseptic properties which appealed to him as the fact that they practically reduced the inflammation of the urethra; in this respect permanganate of potassium seemed to stand out above all others.

Dr. A. S. PLANT (Grimsby) said that the development of a peri-urethral abscess, if got under control in time, and aspirated in such a way that it did not burst into the urethra, afforded an admirable and rapid means of curing the gonorrhoea. He assumed that the abscess caused the rapid formation of antibodies, and he suggested that it might be worth while to create an artificial gonococcal abscess in some position where it could not communicate with the urethra.

The further discussion, in which several delegates from over-seas participated, tended to stray into the question of administration. Dr. E. T. BURKE (Salford) spoke in praise of detoxicated vaccines, saying that at a certain clinic of which he had had experience, during a period in which vaccines were used there were no in-patients suffering from complications in gonorrhoea, but after the vaccines were stopped on the ground of economy the number of in-patient days during the next twelve months had been 192.

ADMINISTRATION OF VENEREAL DISEASES MEASURES

Colonel L. W. HARRISON (Ministry of Health), in opening a discussion on this subject, said that there were 126 venereal diseases treatment centres in England and Wales under arrangements with voluntary hospitals, and sixty-two conducted by county and county borough councils. There were thirteen hostels for the care of certain girls, not prostitutes in the ordinary sense, and a number of other institutions, together with eighty-five approved laboratories for the examination of specimens. The quality of the work at the treatment centres, of course, depended on the convenience of the premises and the keenness of the personnel, and in both respects he thought that progressive improvement could be claimed since the venereal diseases scheme was initiated. One great obstacle was the idea still prevalent in many areas that efficient treatment of venereal diseases was within the competence of any practitioner who could put a needle into a vein and give an intramuscular injection. Another obstacle was the indifferent supply of real specialists in venereal diseases. Just after the war many medical officers who were interested and skilled in the management of venereal diseases were available, but most of the clinics were already staffed at that time with medical officers who had remained in practice, and most of these others reverted to general practice. Since then there had been no rush of young men to specialize in venereal diseases. Unfortunately this was the Cinderella of all medical specialties. It was often said that it was a narrow specialty, but, in fact, it took all one's time to keep abreast of the literature. True, there was not much attraction in venereal diseases for anyone in search of material reward. He desired to see a good working knowledge of venereal diseases made an essential qualification for entry into the public health service. On the subject of the education of the public he touched upon one very definite defect. For every woman under treatment there must be at least one other going untreated. This he concluded from the fact that while in syphilis the ratio of new female cases to new male cases was as 1 to approximately 1.6, in gonorrhoea the corresponding ratio was 1 to 3.9. Women generally were not aware of the importance of having apparently innocent discharges examined.

Surgeon-Commander R. J. G. PARNELL, R.N., gave some account of the factors influencing the decrease of venereal diseases in the Navy. During the last forty years the ratio for syphilis had declined from 51.66 per 1,000 to 5.55, and the ratio for gonorrhoea from 76.87 per 1,000 to 41.58. The factors which had led to the decrease were the changed type of man enlisted, together with his more healthy environment. Prophylactic measures also had had some effect. The naval rating to-day was better educated, more temperate, and keener on games and sport than his predecessor of forty years ago. He felt sure also that the remarkable reduction in the incidence of syphilis was in a large measure due to more efficient treatment of the civil population, whereby that population was rendered less infective.

In the course of discussion, Lieut.-Colonel A. P. G. LORIMER, I.M.S., gave an account of the position in Madras, and maintained that in India the venereal diseases problem could only be efficiently undertaken by a well-disciplined and well-organized State medical service; Dr. J. DANEEL described the conditions in South Africa, especially deploring the absence of facilities for treatment of natives on the Rand; and Dr. C. J. AUSTIN spoke of Fiji. Other speakers, notably Dr. JOHN GUY (Edinburgh) and Dr. W. G. CLARK (Glasgow), discussed the relationship of the venereal diseases officer to the medical officer of health, and a further subject of discussion, largely participated in by Scottish representatives, was as to any means of compelling the continuance of treatment until cure. Dr. Clark urged the separation of syphilis from gonorrhoea administratively, and the taking of measures to deal with syphilis by way of a scheme on a level with the tuberculosis scheme.

Mr. DAVID LEES (Edinburgh), who presided, said that he had a good deal of sympathy with such proposed separation, but more sympathy still for any proposition

to cut out the word " venereal " from the legislation on the subject and from the institutions for diagnosis and treatment. Over 60 per cent. of female patients had not acquired their infection venereally, and it was unfair to expect them to attend a department labelled with that name.

THE DIET OF ANIMALS

The Cavendish Lecture was delivered before the West London Medico-Chirurgical Society on June 29th by Sir PETER CHALMERS MITCHELL, F.R.S., secretary of the Zoological Society, his subject being " The Diet of Animals."

Sir P. Chalmers Mitchell spoke first on the relation between diet and growth. Some mammals, he said, appeared never to attain adult stature. The process of growing slowed down, but death by disease or accident generally overtook them before they had grown as big as they could become. That seemed to be true of the whale, the elephant, and probably the rhinoceros. Where growth was continuous in that way, of course, there was not the change from the fuller diet of youth to the more restricted diet of full growth. In birds the transition from the period of growth to the adult stage was always very definite. Birds attained adult stature very quickly indeed, and there was a fixed average size for every species. Reptiles appeared to have no infantile stage. From the moment of birth or hatching they were small miniatures of their parents, following the same habits and living on the same food. Amphibians, on the other hand, had a definite infantile stage. It was often stated that a number of mammals never drank water. It was true that certain mammals living in desert regions could obtain water only occasionally, but in captivity these animals took every chance of drinking, and often drank to excess. Certain animals were addicted to alcohol. With most creatures it was difficult to get them to take it medicinally, but certain groups of animals liked it instinctively ; these included the asses and zebras, and elephants also showed addiction. It was worth remembering that the digestive processes of mammals and many other kinds of animals were much more accommodating than might be supposed. A famous case was on record of a French horse which was trained for the Derby on a purely nitrogenous diet and did well. John Hunter fed a gull entirely on grain, and beyond changing the character of the lining membrane of its stomach, did it no harm. The distinction between carnivorous and herbivorous animals also was not as clear as was often supposed. Apes and monkeys as a whole were quite definitely vegetarian, but the lower ones would take a good deal of insect food and grubs, and the big apes would eat small animals. A fine pair of gorillas were brought up in the French Congo by a Frenchman and his wife on the ordinary diet of meat, fish, and vegetables which they themselves consumed. The larger carnivora—lions and tigers—seemed to be immune to the whole group of ptomaine poisons ; on the other hand, the smaller cats were extremely susceptible. The true carnivora were carnivorous with a tendency towards vegetable diet, and the big ruminants, like horses and asses, zebras, and the rhinoceros and the hippopotamus, while as a rule pure vegetable feeders, showed now and again examples of omnivorous eating.

The lecturer went on to point out that the alimentary tract of all these animals was accustomed to deal with a very rough kind of diet—a diet of large bulk for the nutriment it contained. Monkeys in the wild did not get nice tomatoes, beans, and lettuces, but fed on hard banana leaves, shoots of trees, and roots of all kinds, and the structure of their intestinal tract was arranged to deal with hard and unnutritious food. When cultivated food, such as cereals, bread, and fruit, which was very nutritious in proportion to its bulk, was given to them they tended quickly to become over-fed, with fatty degeneration of the liver ; or if a smaller bulk of food with the proper amount of nutrition was given peristalsis did not take place normally. Not sufficient attention was paid, perhaps even in human dietary, to the necessity of getting indigestible bulk with the nutritive element.

Reviews

HEART RATES

In their work *The Heart Rate*[1] BOAS and GOLDSCHMIDT have made a very interesting study. Using an apparatus which they have invented and called the cardiotachometer, they have been able to obtain records of the heart rate over long periods of time. The heart currents are led off the chest by electrodes placed over the heart and the currents activate a recording apparatus after suitable amplification. In the space at disposal it is only possible to touch briefly on the numerous interesting records obtained by these workers. They have recorded the rate of the heart in healthy and in diseased persons in almost every possible circumstance and activity. In healthy men they found that the average rate during sleep was 59, and in women 65. During the day's activities the range of the heart rate is remarkable, the average maximum and minimum rates in males being 111 and 61 respectively, with 120 and 53 for females. Attempts were made to correlate the heart rate with bodily measurements. They came to the conclusion that it was unlikely that any anatomical measurements had any direct relation to the heart rate. As regards blood pressure, the lower pressures seemed to be associated with the slower rates.

Extensive observations were made of the heart rate during sleep. The lowest rates were recorded after about five hours' sleep. The deeper the sleep the slower was the rate. Posture during sleep had no effect, but movements caused acceleration. The authors conclude that the slowing of the heart during sleep is the result of passive relaxation of activity, and also of active vagal inhibition. Many records were taken of subjects in their daily activities. Action leads to increase in heart rate by loss of vagal tone, and by acceleration due to increase in venous return. It was remarkable how the ordinary activities of the morning toilet led to cardiac acceleration. Studies of heart rate during eating, micturition, defaecation, coitus, and so forth were also made. Under anaesthesia the heart rate was usually constant once induction was complete. Interference with viscera sometimes caused slowing. In disease, confirmation of the value of ascertaining the sleeping rate in diagnosing doubtful cases of myocarditis was obtained. The persistent tachycardia of thyrotoxicosis during sleep was noted. Records demonstrating the instability of the ventricular rate in auricular fibrillation were obtained. The importance of nervous influence causing undue acceleration in this condition are well shown.

The book is full of valuable and helpful information on a subject of great practical importance. Perusal of its pages will bring home the necessity of remembering the effects of small everyday things of life upon the action of the heart. It is thus of much value, both for the cardiologist and for the ordinary practitioner.

RADIOGRAPHY OF THE LUNGS

The monograph on The Value of Radiographic Examination in Diagnosis of the Lungs,[2] by TORLEIF DALE, is published as the sixteenth supplement of the *Acta Radiologica*. The author, having found that the interpretation of lung radiographs presented many difficulties, has made a special study of the subject, extending over the past three years, with the object of correlating

[1] *The Heart Rate.* By E. P. Boas, M.D., and E. P. Goldschmidt, Ph.D. London: Baillière, Tindall and Cox. 1932. (Pp. 166 ; 30 tables, 68 figures. 18s. 6d. net.)

[2] *Der Wert der Roentgenuntersuchung in der Lungendiagnostik.* Von Torleif Dale. *Acta Radiologica.* Supplementum XVI. Stockholm: P. A. Norstedt und Söner. 1932. (Pp. 111 ; 57 figures. 10 Swedish Crowns net.)

radiographic appearances with anatomical and pathological findings. He stresses the fact that pathological anatomy is an invaluable aid to radiological diagnosis, and that this is true not only as regards the lungs but with respect to pathological changes in other organs, a correct diagnosis being arrived at only by the correlation of radiology and pathological anatomy. The work is beautifully illustrated, and the author has made use of abrodil injections of the bronchi to illustrate the main points in his thesis. Most of the inflammatory conditions of the lungs and pleura are described, and, by comparing the radiographs taken during life with radiographs taken of post-mortem specimens, much new and interesting information has been obtained. This has enabled the author to come to definite conclusions both regarding lung changes which can be diagnosed in a radiograph and, what is equally important, those changes that lie outside the realm of radiology. The monograph can be highly recommended to all those interested especially in diseases of the lungs.

CARE OF HANDICAPPED CHILDREN

The White House Conference on Child Health and Protection has been responsible for many tens of thousands of printed words and for the accumulation of much statistical and other knowledge, of more or less reliability, concerning social and educational conditions in the United States of America; but the ideas and suggestions for action arising therefrom have for the most part been of a vague, platitudinous, and axiomatic character. This remains true of the most recent report of the Committee on Physically and Mentally Handicapped Children, now published under the title *The Handicapped Child*.[3] At the beginning of the volume there are printed the names of no fewer than one hundred and forty-five persons who were members of "Committee B" in its various sections, and no doubt each of these may be credited with some measure of responsibility for the report, but a large share in shaping its final form doubtless remains with Dr. William J. Ellis, its chairman, and Emil Frankel, its research secretary. The children of America are again apostrophized as those "whose faces are turned towards the light of a new day and who must be prepared to meet a great adventure." Over and over again it is emphasized that handicapped children are entitled to care, treatment, and training, both for their own sakes and in order that they may become an asset to society instead of a liability. In this country we do not regard either the importance or the rights of childhood as needing quite so much reiteration. The varieties of handicap from which children may suffer are passed in review, each on a similar pattern—defects of hearing and of vision, crippling deformities, internal conditions such as those arising from tuberculosis, heart disease, and internal parasites, mental abnormalities, and mental deficiency. The results of inquiry into the prevalence and distribution of these in the United States are set down, their possible causation, the present means of dealing with them, and directions in which an extension of these is needed, are noted, and there is a final chapter on vocational guidance.

Apart from the convenience of an orderly assemblage of such particulars as these in one volume, the most valuable and interesting features of the book will be found in the chapters on mental health and mental deficiency. Indeed, the earlier part of the former of these chapters may be said to be of real importance, since it presents very effectively several aspects of the truth which too frequently pass unregarded or unrecognized. There is a definition of mental health as "that adjustment of human beings to themselves and to the world at large which results in a maximum of personal and social effectiveness and satisfactions," and the implications of this definition are wisely enlarged upon. "Nothing can be more fallacious than the interpretation of mental health in strictly individualistic terms. Positive mental health is but the personal aspect of a society in which personal and social values are in right relation to each other and are attainable by everyone within the limits of his biological capacities." So, with regard to mental deficiency there is reasonable estimation of its meaning and prevalence and of its relation to mere dullness and degrees of intelligence. Its hereditary causation and its social and racial consequences are not over-emphasized as is so commonly done. Though a very carefully selective sterilization is on the whole approved, its strict limitations of value, both individual and racial, are stressed, and the urgent need for further knowledge and research into the character and causation of the varieties of mental deficiency is insisted upon.

BUCCO-DENTAL PATHOLOGY

Pathologie Buccale, Péri-buccale et d'Origine Buccale[4] is the first of a series of nine volumes entitled "Pratique Stomatologique," and owes its production to Drs. ROUSSEAU-DECELLE and RAISON. The whole work is published under the direction of Dr. Chompret, who has chosen as his collaborators men having personal experience who will deal with their own specialties. The present volume is divided into two parts, the first dealing with buccal and peribuccal pathology, and the second with general pathology in relation to bucco-dental pathology. The authors throughout have justified the confidence of their chief. On every page one finds evidence of mature thought and wide observation. Of this the chapter on stomatitis is a good example. According to the authors, one form only can be considered primitive—aphthous stomatitis; the ground is generally prepared for the others by the existence of a tartar-stomatitis. Aphthous stomatitis itself is carefully compared with foot-and-mouth disease, and the conclusion is reached that it is a virus disease but that the virus is entirely distinct from that of the cattle disease. It is interesting to note that, contrary to British experience, the authors' observations lead them to conclude that a high palate is a stigma of degeneration, found in idiots, epileptics, cretins; that it is also often a consequence of rickets, and very often a dystrophic sign in hereditary syphilis.

On reading the second part of the volume it becomes evident that the authors are acutely aware of the dangers of dental sepsis, and one gathers that they regard pyorrhoea as at least as injurious as "dead teeth." In a note on edentulous dyspepsia and fetid diarrhoea the observations of Roger on the activation of pancreatic juice by salivary ferments are quoted (Roger found that the salivary ferment passes through the stomach and doubles the action of the pancreatic juice on fats) as showing the necessity for thorough mastication. To whatever disease one turns one finds the same succinct and thorough review of the salient points. The authors are to be congratulated on the good work they have done.

DISEASES AND INJURIES OF THE EYE

The new book in the Practitioner's Series on the *Diseases of the Eye*,[5] by Mr. RUGG-GUNN, presents many attractions. It deals essentially with diseases and injuries, and their prevention and treatment. So that whilst there is a good general account of the meaning and effects of

[4] *Pathologie Buccale* Par les Drs Rousseau-Decelle et Raison La Pratique Stomatologique, I Paris Masson et Cie 1933 (Pp 576; 196 figures Broche 70 fr. relie toile 85 fr.)

[5] *Diseases of the Eye* By A Rugg-Gunn, M.B., F.R.C.S. Practitioner's Series London W Heinemann, Ltd 1933 (Pp. 188. 21 figures, 8 plates 12s 6d net)

errors of refraction no attempt has been made to give instruction in the methods of determining these errors. Again, there are clear and useful accounts of the means of detecting defects of muscle balance and their treatment, and also of patent squint, but details of operative methods are omitted. This selection has allowed the author to concentrate upon the main theme of his book. In the consideration of diseases and injuries an excellent perspective is maintained. The more common diseases are described with nicety ; their causes and relations to general bodily conditions and social states are clearly and tersely indicated. Treatment is considered at length, and the lines suggested are thoroughly modern and practicable. Diseases of less frequent occurrence are brought into review more as a means of suggesting caution in diagnosis, and this is as it should be in a work of this character. Despite the necessarily limited compass of the book, it amply fulfils its purpose. It is well written, and the author has the power of conveying his meaning to his reader with a minimum of words. There are few books of this order which can be read with more pleasure and profit: it is not merely a short index of ophthalmic treatment.

The make-up of the book is excellent: good paper, legible print, and plenty of clear illustrations. The figures are all reproduced in black-and-white, including the fundus drawings, which are none the less as characteristic as though they had been done in vivid colour. In a future edition the author might consider the desirability of breaking up the series of illustrations on page 143 (showing the true and false images found in paralysis of external ocular muscles) and setting the legend of each condition under its appropriate figure. Diagnosis of paralysis is a veritable maze to the student, and grouped figures with detached captions are not helpful.

Notes on Books

In a reprint of a series of wireless talks entitled *From a Doctor to a Mother*,[6] the British Broadcasting Corporation has included short lectures by Mr. EARDLEY HOLLAND, Dr. REGINALD JEWESBURY, and Dr. WILFRED SHELDON. They deal with the management of maternal and infant health from the early months of pregnancy to the end of the second year of the child's life. Mr. Eardley Holland has dealt with the period before birth, laying down clear rules for the guidance of the mother and striking a reassuring note throughout. Dr. Jewesbury has covered the difficult ground of natural and artificial feeding concisely and with unusual simplicity ; there is nothing here to bewilder the inexperienced mother, and much to help her. He includes appropriate menus for the child from the age of 8 months to 2 years and over. In the final chapters Dr. Sheldon touches on normal development, disturbances of sleep, and the prevention of nervous habits. The book is fitted quite admirably for its purpose, which is to supplement the advice of the patient's own doctor and nurse, and it deserves to be used widely in welfare centres.

The number of names in the *Dentists Register*[7] for 1933 is 14,528, an increase of fifty-six over the figure for the preceding year. Of these there are 7,500 (51.62 per cent.) registered with medical, surgical, or dental qualifications, as compared with 7,304 in 1932. Only six out of the 248 new British entries in the last twelve months did not hold such qualifications. Death and other causes were concerned in the removal of 476 names ; 282 which had been omitted from previous editions for various reasons now reappear. The *Register* this year contains an " Important Notice " on the liability to disciplinary action in cases of covering, advertising to obtain patients, canvassing, improper announcements regarding branch practices, the incorrect use of titles, notices about insurance practice, commission paid or allowed in return for the recommendation of patients, and convictions for drunkenness as well as for graver offences.

The second volume of the *Royal Berkshire Hospital Reports*[8] has now appeared. Most of the papers were read at meetings of the Reading Pathological Society, and thus this volume serves as its Transactions. Copies may be obtained from the secretary at the hospital. For financial reasons it has been decided to issue the next two volumes together in 1935. As in the first volume, the present one comprises records of cases, as well as lectures on clinical and pathological subjects.

Preparations and Appliances

TWO-WAY URETHRAL CATHETER AND THERMO-FLASK RETAINER

Mr. MORTON WHITBY, chief assistant to the genito-urinary department, West London Hospital, writes: I have had made for me to my design a soft rubber two-way urethral catheter and thermo-flask retainer, as shown (*in situ*) in the accompanying sketch, for the purpose of obtaining heated fluid continuous urinary bladder irrigation in cystitis, preoperative treatment in bladder operations, and to enable the complete closure of the bladder after cystotomy, especially in cases of prostatectomy.

The catheter is made of soft rubber and is of ordinary length. It has an inlet equivalent to size No. 3 catheter and an outlet in sizes varying from No. 10 to No. 15. At its terminal end there is a small eyelet for the inflow, and two eyelets for the outflow, their position arranged as in the diagram. The tube from the thermo-retainer is fitted with a stopcock which will regulate the inflow in cubic centimetres per minute. The outflow passes through a tube which is connected at its end to an S-shaped tube, and passes into a pail of antiseptic fluid. The flow is started by turning on the stopcock to the required rate and, after a short flow, using suction on the outlet, when the flow will be continuous. Blockage can be prevented by reversing the flow for a few minutes every half-hour or so. The best rate is 8 c.cm. per minute, which just keeps the bladder moist and washes away all debris. If the condition of the bladder is bad the rate of flow should be increased. If it is desired to keep the bladder dry a Cathcart's apparatus can be used with the catheter. The catheter is retained by zinc plaster.

The entire apparatus is made by W. Gimber and Son (2, Queen's Road, Peckham, S.E.15).

ONE HUNDRED AND FIRST ANNUAL MEETING

of the

British Medical Association

DUBLIN, 1933

THE one hundred and first Annual Meeting of the British Medical Association will be held in Dublin this month under the presidency of Dr. T. Gillman Moorhead, Regius Professor of Physic, Trinity College, who will deliver his address to the Association on the afternoon of Tuesday, July 25th. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoon to demonstrations. The Annual Representative Meeting for medico-political business will begin on the previous Friday, July 21st. The lists of officers of the sixteen Scientific Sections and the subjects for discussion, together with other information about the meeting, were published in the SUPPLEMENT *of July 1st.*

We publish below the fifth of a series of descriptive articles on Dublin and its medical institutions. The first appeared in our issue of December 3rd, 1932 (p. 1026); the second, on the History of Dublin, on March 18th, 1933 (p. 476); the third, on the Dublin of To-day, on April 22nd (p. 710); and the fourth, on the University of Dublin, on May 13th (p. 837).

THE SCHOOLS OF MEDICINE IN DUBLIN IN THE NINETEENTH CENTURY

BY T. PERCY C. KIRKPATRICK, M.D., M.R.I.A.,
Fellow and Registrar of the Royal College of Physicians of Ireland

The nineteenth century witnessed many changes in the social, economic, and political conditions of Ireland, but in none of these was the change more pronounced than in the teaching of medicine. When the University of Dublin and Trinity College were founded in the last decade of the sixteenth century they were given the privilege of conferring degrees in all faculties, but this privilege was largely neglected, and the University remained content merely to grant degrees in the faculties of arts and theology, while there was little or no pretence of teaching any other subject. As Provost Bedell said in 1628, Trinity remained "one poor College of Divines." The foundation during the Commonwealth of the Fraternity of Physicians, which, after the Restoration, was incorporated as the College of Physicians, led to some teaching in medicine, but such teaching was unsystematized, and amounted to little more than a few anatomical demonstrations and an occasional public lecture. Early in the eighteenth century, mainly through the influence of Sir Patrick Dun, a medical school was started in Trinity College, and Dun bequeathed to the College of Physicians a considerable sum of money to assist the development of medical teaching.

The medical school of Trinity College, started under excellent auspices, did not fully justify its early promise. Disputes between the Board of Trinity College and the Fellows of the College of Physicians, the two governing bodies of the school, greatly hampered progress, and at one time threatened extinction of the school. In the early part of the second half of the century, while George Cleghorn was lecturer in anatomy, the school became a centre of anatomical teaching of considerable importance, but even then the want of harmony among the teachers prevented its full development in other directions. As the century drew to a close this disharmony became accentuated, and after the death of George Cleghorn the school dwindled almost into insignificance. The efforts made to develop clinical and practical teaching in medicine failed hopelessly owing to the disagreement of those who held professorial chairs in the school. In 1800 the Irish Parliament, just before it disappeared, passed an Act which alienated the greater part of Dun's estate from the teaching of medicine, and applied it to the building and the endowing of a hospital where clinical lectures might be given. This project, prompted by the jealousy of Robert Perceval, was carried out in spite of the opposition of the College of Physicians, and in spite also of the fact that there were already in the city several hospitals, each of which might better have fulfilled the purpose for which the new hospital was designed.

MEDICAL CORPORATIONS IN THE EIGHTEENTH CENTURY

During the eighteenth century whatever surgical education there was had been under the control of the barber-surgeons or the Guild of St. Mary Magdalene, which had been founded by Henry VI in the year 1446, reincorporated by Elizabeth in 1572, and granted a new charter by James II in 1687. Surgeons learned their art as apprentices to members of the Guild, and even when the Guild began to lose its authority and to become more and more a political caucus, the regulations for apprenticeship continued strictly to be maintained. An examining board, constituted by Act of Parliament to select surgeons for the newly established county infirmaries, rejected a larger number of candidates for not having fulfilled their indentures than for lack of knowledge of surgery.

On February 11th, 1784, as the result of a long-sustained agitation, a number of Dublin surgeons were incorporated by charter as the Royal College of Surgeons in Ireland, with the special objects of establishing a school for the teaching of surgery and of granting licences to practise to properly qualified surgeons. Almost immediately after incorporation the College of Surgeons started a school, but it was not until the new century had commenced that suitable premises were provided for it and a great teacher arose who was to gain for the school a world-wide reputation. Although in practice the foundation of the College had separated the surgeons completely from the barbers, yet nominally they remained united until the city guilds disappeared in consequence of the passing of the Municipal Corporations (Ireland) Act in 1840.

In 1745 George II incorporated the apothecaries, who had previously been united with the barber-surgeons, as a separate guild, the Guild of St. Luke. This was the last guild to be constituted in Dublin, and its members do not seem to have been very popular. In some verses on the Riding of the Franchises, published anonymously in 1767, it is said:

> "See, where the proud Apothecaries drive.
> Who most by fraud and imposition thrive.
> Whose monstrous bulls immoderate wealth procure
> For drugs that kill as many as they cure
> Well are they placed the last of all the rout,
> For they're the men we best can do without."

In this procession the barber-surgeons followed the smiths, fourth in the list of the twenty-five city guilds, but in describing them it was their barber-craft, and not their surgery, to which the writer of the above lines referred. In 1791 the Dublin apothecaries were incorporated as the Governor and Company of the Apothecaries' Hall, and although, like the Guild of St. Mary Magdalene, the Guild of St. Luke persisted till 1840, the new company took over any of the remaining professional activities of the guild. The Act of 1791 granted to the Apothecaries' Hall powers for licensing persons to practise as apothecaries in Ireland, but such persons, as a matter of fact, engaged largely in the practice of both medicine and surgery. Although making a licence to practise compulsory, the Act did not lay down any definite curriculum for those seeking the qualification. The Company, however, set up a Hall in Mary Street, Dublin, and appointed William Higgins as chemist. Higgins apparently had some duties to perform as a teacher, but there was no regular school attached to the Hall until 1837.

Thus at the end of the eighteenth century there were four corporations in Dublin—the University, the King and Queen's College of Physicians, the Royal College of Surgeons, and the Worshipful Company of the Apothecaries—all of which were interested in the teaching and licensing of those seeking to practise medicine and surgery. The University and the College of Physicians had joint control of the School of Physic, while the College of Surgeons had complete control of its own school. The Company of Apothecaries had not then established any school for its students, who had to learn their business as apprentices.

MEDICAL TEACHING IN THE NINETEENTH CENTURY

The great movement in the British Isles for the establishment of voluntary hospitals, which originated in Dublin in the first decade of the eighteenth century, had resulted in the foundation of six general hospitals for the treatment of the sick and poor in the city. There were, besides, a large lying-in hospital, an asylum for the reception of the insane, a hospital for incurables, a Lock hospital for both men and women, and a military hospital for the reception of soldiers of the garrison. At least two public dispensaries for the treatment of the poor as extern patients were also largely attended. Dublin had even then pledged itself to the principle of having many small institutions for the treatment of the sick rather than a few large ones, a principle which has since been maintained, not without success. Although hospital attendance was not required from the students by the licensing bodies, yet many students, especially the apprentices, attended these hospitals, and there learned, practically, their work. The number of institutions which were engaged both in teaching students and in treating the sick afforded opportunity to the physicians and surgeons of Dublin to prove their worth, and the competition for the more valuable posts encouraged hard work among those who were anxious to outstrip their rivals. The slack and the incompetent were easily detected by the public when compared with the energetic and resourceful men who were pressing forward under the stimulus of a laudable ambition. About this time, too, there grew up a tradition, which since has become well established in Dublin, that for newly qualified men private teaching is not only profitable, but is also the surest way to preferment in the profession. Private teaching was not then hampered with any strict requirements enforced by the examining and licensing bodies; provided an apprentice had properly completed his indentures, and the student could answer the theoretical questions put to him by his examiners, there was little effort made to test his practical knowledge, and no inquiry was made as to where or how he had learnt his work.

During the first quarter of the nineteenth century all these resources for teaching and for the treatment of the sick were used to their full capacity, yet, in spite of them, the demand for teaching was soon to exceed the supply. It is not possible to make an accurate estimate of the number of persons in Ireland who, during the eighteenth century, were anxious to study medicine, but that the number was considerable is shown by the figures which are available. During the fifty-two years 1748 to 1800, 293 Irish students took the M.D. degree in the University of Edinburgh, while many others graduated in Glasgow and Aberdeen; quite a large number went to universities on the Continent, where those who professed the Catholic religion had perforce to seek the education which was denied to them at home. The European war in which England was engaged at the time had created an urgent demand for Army medical officers, while the existence of that war made it more difficult for Irishmen to get medical education abroad. Dublin had also the advantage of being well supplied with the material for the study of human anatomy, and indeed for many years before the passing of the Anatomy Act a considerable export trade in that material was done from Ireland to both England and Scotland.

At the opening of the nineteenth century neither the School of Physic nor the school of the College of Surgeons was in a very active state. The latter school was hampered by insufficient accommodation—it was not till 1809 that the new buildings in Stephen's Green were ready for use. In the School of Physic James Cleghorn, nephew of the great George Cleghorn, was professor of anatomy and surgery, but he was in bad health, and his teaching work had largely devolved on his assistants, one of whom, William Hartigan, was to succeed him and to hold the chair till the end of 1812. Edward Hill and Whitley Stokes both held chairs in medicine in the school, but their lectures, both systematic and clinical, were delivered in Latin, in which language the examinations were also conducted; it was not until 1831 that the College of Physicians agreed to allow English to be used instead of Latin in the examination of candidates for their degrees. All students who wished to graduate in medicine in the University had first to graduate in arts.

It is not surprising that, with these restrictions, the classes in the School of Physic were small, and during the last fifteen years of the eighteenth century only seventy students entered the school, or less than an average of five each year. A great change took place in the second and third decades of the nineteenth century while James Macartney held the chair of anatomy, for in 1829 the number of students studying medicine in the School of Physic was 303. In the school of the College of Surgeons there was a similar expansion. In the session 1799-1800 the number studying in the school was sixty. In 1805 Abraham Colles became professor of anatomy, and in the session 1809-10 the class numbered 162; in the next year it numbered 185, and in the year after 201. Two such teachers as Macartney and Colles quickly made Dublin a favourite centre for medical students, who flocked to it from all parts of the United Kingdom. Their very number, however, seemed to be likely to prove the undoing of the schools, since it was difficult to find accommodation for them at the lectures and in the dissecting rooms, and as the choice of where he would go rested with the student, he would not attend where he thought he would not get good value.

PRIVATE MEDICAL SCHOOLS

Teaching medical students had thus proved itself to be a profitable employment, and a good teacher in anatomy or surgery or medicine could be sure of a good income. Except for anatomy, a little chemistry, and some operative surgery on the dead subject, the teaching was entirely theoretical, and did not need any apparatus. A lecture room, a dissecting room, a small chemical laboratory, and a museum fulfilled all the requirements of a school of medicine. Medical men soon recognized how easy it was to open a school to which, if they were good teachers, they could attract a large and a paying class of students. In consequence we find that quite a large number of private schools were started in Dublin, sometimes in connexion with a hospital and sometimes purely as a private venture. For success it was essential that the certificates issued for attendance at these schools should be recognized by the licensing bodies as permitting students to

enter for the qualifying examinations, and by the Army authorities as qualifying for commissions in the Army Medical Service This essential was, however, easily satisfied

Crampton's and Kirby's Schools

One of the first of these schools to be opened was Crampton s School, which Philip Crampton opened in 1804 in the stable at the back of his house at 42, Dawson Street In this school anatomy, physiology, and surgery were taught, and there quite a number of students entered This school, which was closed in 1813, was intimately connected with the Meath Hospital, where Crampton was surgeon In 1808 a school of anatomy was opened in connexion with Jervis Street Hospital, it lasted till 1833 In the following year, 1809, one of the most celebrated of the private schools, the Theatre of Anatomy, was opened by John Timothy Kirby and Alexander Read in Stephen's Street In 1810 it was moved to 28, Peter Street, its name was changed to the Theatre of Anatomy and School of Surgery, and shortly after Kirby became sole owner In order to satisfy the requirements of the Army authorities of the time Kirby found it necessary to establish a hospital in connexion with his school He dedicated it to SS Peter and Bridget, and maintained it out of the profits of the school Kirby s enemies maintained that the hospital contained only one bed Kirby's school attained a great reputation, especially with candidates for the Army Medical Service It is related that at his lectures he used to fire a pistol at a body placed against the wall, when the body fell it was examined as a soldier would be on the field, and the bullet was located and extracted in the presence of the students The entire performance was staged with great dramatic effect A successful teacher —and Kirby was very successful—was always a serious rival to the School of Physic and to the College school Such competition was usually overcome by inducing the successful teacher to join one or other of these schools, and at length, in 1832, Kirby was tempted to accept the chair of medicine in the College of Surgeons, his school in Peter Street was then closed, and his museum was transferred to the College

In 1812 a school was started in connexion with the House of Industry Hospitals, at first called the School of Medicine Hardwicke Hospital, and shortly afterwards the Anatomical Theatre of the Richmond Hospital In 1826 this school was housed in Channel Row, just opposite the Richmond Hospital, and was then known as the Richmond Hospital School One of the best known teachers in this school was Richard Carmichael, surgeon to the Richmond Hospital In June, 1849, Carmichael was drowned while riding across the strand from Clontarf to Sutton, in his will he bequeathed a sum of €10,000 to the Richmond School, and in consequence of this generous bequest the name of the school was changed to the Carmichael College The money did not become available till 1864, when new school premises were built in North Brunswick Street In 1879 the school was again moved to premises especially built for it in Aungier Street, at the corner of Whitefriar Street, where it continued to attract large classes till the schools' amalgamation in 1889 Sir John William Moore was for a time professor of medicine in the Carmichael College

Private schools were established also by A Calonne in South Great George s Street (1815 33), by William Wallace in Moore Street (1820–37), on Lower Ormond Quay in connexion with St Mary's Eye Hospital (1820–7), and in Eccles Street by Ephraim McDowel and Robert Adams (1822–6) In 1824 an important school was opened in a new building in Park Street, now Lincoln Place This school, known as the Park Street School, was founded by James William Cusack and Samuel Wilmot (surgery), Robert James Graves and Henry Marsh (medicine), Samuel Athanasius Cusack (midwifery), James Apjohn (chemistry), and Arthur Jacob (anatomy and physiology) The Park Street School attracted a large number of pupils, but its professors were rapidly absorbed by both the School of Physic and the College of Surgeons In 1849 Hugh Carlisle, who had become the chief proprietor of the school, was appointed professor of anatomy in the newly established Queen's College, Belfast, and Park Street School was closed, the museum being sold to Belfast for £250 The school building subsequently b came the home of St Mark's Ophthalmic Hospital, and now forms the chambers to the east side of the Lincoln Place gate of Trinity College

In 1827 a school was opened in Bishop Street attached to the Anglesea Lying in Hospital, the chief proprietor being George Thomas Hayden In 1836 this school was closed, when Hayden moved to 28, Peter Street, the house which had been occupied by Kirby s school At the time there was a private school next door in No 27, owned by Andrew Ellis and John Edward Brennan, in order to distinguish his school, and to attach to it some of the traditional glory of Kirby, Hayden called his the Original School of Medicine In 1849 Thomas Hawkesworth Ledwich became lecturer in anatomy in the school and one of the chief proprietors Ledwich, who was very popular, died on September 29th, 1858, and in his memory, at the request of the students, the name was changed to the Ledwich School, a name which it retained until 1889 when, with the Carmichael College it was united to the school of the Royal College of Surgeons Three other important schools were opened in Dublin during the century In 1837 the Apothecaries Hall started a school in Cecilia Street For a few years this school attracted a considerable number of pupils, but after Benjamin Alcock, the professor of anatomy and physiology, was appointed to the chair in Queen's College, Cork, the classes dwindled away, in 1854 the school was closed and the premises were sold to the Catholic University

Catholic University School of Medicine

The Queen s Colleges of Cork, Galway, and Belfast, started by Sir Robert Peel in 1845, and five years later constituted the Queen's University of Ireland, had made no provision for medical education in Dublin The whole idea of the Queen s University was repugnant to the Catholics of Ireland, and neither the University nor the Colleges received much support from Catholic students either in arts or in medicine This failure of the Queen s University to satisfy the requirements of the people led to the establishment by Pope Pius IX in the years 1851 4 of the Catholic University of Ireland, under the directorship of John Henry Newman It was hoped that this university, although supported merely by voluntary contributions and without a charter, would form a great centre for the higher education of Catholic students of Ireland In spite of the fact that in 1853 Newman had gathered a brilliant staff and was himself a most enthusiastic leader, the new university did not altogether realize the great hopes of its founders It did, however, become the Alma Mater of two great schools which have made a lasting impression, both in arts and in medicine, on higher education in Ireland From the Catholic University sprang University College, Dublin, and the Catholic University School of Medicine, both now joined as a constituent part of the National University of Ireland The premises in Cecilia Street, purchased from the proprietors of the school of the Apothecaries' Hall, were refitted, and in 1855 they were opened as the home of the medical faculty of the Catholic University From the first this school proved to be a great success, and even when the fortunes of the University were declining the medical school maintained its high reputation The Royal University Act of 1879 through which the Royal University came into being in 1882, replacing the Queen's University, brought the arts department of the Catholic University—which had then been put under the management of the Order of the Society of Jesus and renamed University College—and the medical school in Cecilia Street into close relation with the new university as its chief feeders in Dublin The closest co operation was maintained between University College and the medical school so that the students of the latter were taught the preliminary subjects of their first year in the arts classes of University College In 1909, when the National University of Ireland came into being, University College and the Catholic University Medical School united to form the faculties of arts and medicine in one of its three constituent colleges

Steevens' Hospital School

The last private medical school to be established in Dublin was the Steevens Hospital School, founded in 1857. Towards the middle of the eighteenth century the Irish Parliament had begun the practice of making money grants to certain hospitals in Dublin, and after 1800 the practice was continued by the Parliament of the United Kingdom. These grants were made to certain hospitals in quite an arbitrary manner, as the result of a petition made each year by the hospital to Parliament. The discrimination in making these grants led to much comment, and indeed it is difficult to see how the awards were justified. In 1842 the Lord Lieutenant appointed a commission to inquire into the condition of those hospitals to which grants were made, and, this being an Irish Commission, it reported strongly in favour of the continuance of the grants. In spite of this report, however, the House of Commons in 1851 resolved that a yearly reduction of 10 per cent. should be made in all the grants until they were finally extinguished, and for some years after such a reduction in the grants was made.

In 1855 the Lord Lieutenant appointed three commissioners to report on the hospitals which were receiving grants, and directed them to give special attention to two points: (1) whether any of these institutions could, with advantage, be closed, and (2) how any money which Parliament might recommend could be best spent to assist in the advancement of medical science. Of these three commissioners the active member seems to have been John Flint South, surgeon to St. Thomas's Hospital, London. In their report the commissioners stated that there were great difficulties in the way of closing any of the institutions, but they recommended certain modifications in the grants, and that a Board of Superintendence should be set up to inspect and to report on those institutions which received the money. In the case of Steevens' Hospital they recommended that the grant—then £1,080 a year—should be increased to £1,300 a year if a medical school were established in connexion with the hospital, and in an appendix to the report South submitted a detailed scheme for the establishment of such a school. The Board of the hospital accepted the proposals, and in 1857 the school was opened. During the first year seventy-four students were enrolled. At the time there were in Dublin five active medical schools—the School of Physic, the school of the College of Surgeons, the Carmichael College, the Ledwich School, and the school of the Catholic University—so that it is difficult to see why South should have wished to add to this number. Probably he was influenced by the success of the schools attached to the great hospitals of London, and, like many another Englishman before and since, he believed that all difficulties in Ireland could be solved by the adoption there of plans which had been found to suit in England. Steevens' Hospital School, however, proved to be a great success, and during the twenty-three years of its existence (1857-80) it had an average attendance during the winter sessions of sixty-nine and during the summer sessions of thirty-five students. Eventually failure of the Board of the hospital to work harmoniously with the school committee led, early in 1880, to the resignation of the professorial staff, and the Board closed the school at the end of the summer session of that year. In the last year of its existence there were in the winter session fifty-five and in the summer session thirty-seven students attending.

The College of Surgeons' School

Of the nineteen more or less complete schools of medicine which were functioning in Dublin between 1800 and 1860 five remained after 1880—the School of Physic, the school of the Royal College of Surgeons, the school of the Catholic University, and the two proprietary or private schools—the Carmichael College and the Ledwich School. The increase in practical teaching and in laboratory work, especially in the subjects of pathology and physiology, and the greater scarcity in the supply of subjects for dissection, made it more and more difficult to carry on at a profit a school which was supported merely by the fees of the students. Even the College of Surgeons felt this strain, and as early as 1882 the suggestion was put forward that the College should hand over its school to the professors, giving up all collegiate interest in it, and thus get free from all financial responsibility for it. This suggestion was bitterly opposed, and was finally abandoned. Two years later it was suggested that the College School should be amalgamated with the Carmichael and Ledwich Schools, but this proposal was also turned down. The financial difficulties in the way of such an amalgamation seemed to be almost insuperable owing to the vested interests of the proprietors and the professors in the two private schools which would have to be purchased. The matter, however, was not allowed to rest, and on May 21st, 1888, the fellows of the Royal College of Surgeons adopted the following resolution:

> "That having regard to the interests of medical education in Dublin it is desirable to diminish, as far as possible, the number of private schools; and that with a view to carrying out this principle it be an earnest recommendation to the Council to take such steps as may be necessary to effect on equitable terms an amalgamation of the existing private schools with the school of the College of Surgeons."

The discussions which the carrying out of this resolution involved continued over a year, but at last, on September 14th, 1889, the Council of the College finally approved the scheme of amalgamation, and on November 1st, 1889, the three schools started work under one management. The cost was great and for some time it proved a source of considerable financial embarrassment to the College.

The nineteenth century had opened with two medical schools in Dublin, the School of Physic and the school of the Royal College of Surgeons, neither of which was in a very efficient state; it closed with these two schools still in existence but much more efficient, and, in addition, in Cecilia Street, the active and flourishing school of the Catholic University. Looking back over the century one can see a long line of highly qualified and gifted teachers, teachers who attracted large numbers of students, and who gave to those students an individual attention and a practical education which has enabled Irish medical men to win for themselves high places in medical circles throughout the world. At the same time these teachers enriched the science which they taught with many original observations of permanent value. The education given was eminently suitable for the ordinary student; it fitted him admirably for general practice, but it did not afford equal facilities to the brilliant student who wished to become a specialist or a research worker. The education had the merit of being cheap, sound, and practical—qualities very necessary at all times. The modern tendency is different. In order to suit the new conditions which have arisen concentration in larger and more expensively equipped schools has seemed to be necessary, and has proved to be effective. Many believe that a similar concentration in a few large hospitals will be necessary also before clinical teaching in Dublin comes to its full fruition. There is no doubt that the present time, when large sums of money are being made available for the support of the voluntary hospitals, is a suitable time for considering whether or not this change should be made. If it is right that the Dublin system of hospital provision for the treatment of the sick and for teaching purposes should be changed, now is the time to make that change. If the money now being collected is spent, as it is proposed to spend it, in the reconstruction and the re-equipment of the existing hospitals, the opportunity for making such a change will have been indefinitely postponed.

The Princess Royal recently paid an informal visit to the Institute of Ray Therapy and Electro-Therapy in Camden Road, N.W., of which she is Patroness, and was escorted over the building by the hon. medical director, Dr. William Beaumont, and the hon. secretary, Miss Winifred Beaton (Mrs. Beaumont). Her Royal Highness took much interest in the various types of apparatus demonstrated to her in the treatment rooms during her one and a half hours' visit, and asked many questions.

ROAD TRAFFIC SIGNALS

The Departmental Committee of the Ministry of Transport on road traffic signs, appointed in December, 1931, has now reported.[1] Since the purpose of traffic signs is safety on the roads and the prevention of accidents, the report is of special interest to medical practitioners, both because they are users of the roads at all hours and in all weathers and because accidents on the roads make such heavy demands upon their time and skill. The personnel of the committee, to the number of twenty-seven, would appear to be fairly representative of every class of road user, save only the medical practitioner, and of all road-controlling interests. It is a lengthy document and expensively illustrated. The members of the committee were able to furnish most of the information needed for their work; nevertheless, some evidence was received from other bodies—for example, the British Medical Association, through Mr. Bishop Harman, its representative for the purpose. The report enters into considerable detail. The illustrated plans of road junctions, one-way carriage roads, parking places, with the layout of white lines and the distribution of signal-light points in relation to the paths of movement of the traffic, suggest the possibility of the development of a fine winter evening game for the children: one that would surely keep them busy, amused, and perhaps out of mischief. Apart from that, it contains nothing of novelty. A body of practice has been growing up in this country and abroad, and the report is more or less in the nature of a "consolidating act." It seeks to bring into something like order and coherence the present-day rule-of-thumb methods.

The committee holds that traffic signs must fulfil certain requirements: (i) They must be so designed and sited as to attract the attention of the persons for whom they are intended. (ii) Their significance must be clear at a glance. (iii) They must be so placed that sufficient time is allowed for the persons for whom they are intended to adapt their course of action to the indication given. (iv) They must, so far as possible, be erected upon a uniform system, and the use of unnecessary signs should be avoided. The International Convention of 1926 pledged various countries to introduce warning signs, but there was no general agreement on the nature of these signs. On the Continent of Europe the generally adopted warning sign is a triangular plate with the appropriate symbol inside the triangle. In this country hollow triangles with a separate symbol and letters are in favour. In the United States of America there is a strong tendency to discontinue the use of symbols and to rely solely on lettering. A wise warning is given on the misuse of warning signals. If drivers are to respect them they should be significant.

> "There is a not unnatural tendency on the part of some highway authorities to exaggerate the dangerous character of particular places in their areas, and for that reason to erect special danger signals. No doubt it is possible to induce drivers to take extreme care at a particular spot by the use of a sufficiently intimidating array of signs, but such over-emphasis cannot fail to weaken the effect of standard warning signs and on the whole to cause more accidents than it prevents. A similar result must follow the use of warning signs at places where they are not justified. An accident which is due merely to bad driving affords no evidence of the need for a warning sign."

Another wise view is that taken regarding mandatory notices. Certain signs, such as "Turn left," "One way only," though apparently mandatory, are essentially directions and for guidance. Others are in a different category. The significance of the red signal with the word "STOP" fused in the lens is unmistakably mandatory and peremptory. The committee recommends that the direction on the green light of the word "GO" should be removed, because the display of the green light merely permits the driver to proceed if he can do so with safety and should not be regarded as an instruction to proceed on the assumption that the road is clear; and again, it must be clearly understood that the green signal does not imply a right to proceed without taking ordinary precautions. In the committee's opinion no wording of any kind—except the word "STOP" on the red lens—should be used on signals, either on the lenses or elsewhere, with the exception of the words "CROSS NOW" or "DON'T CROSS" on the pedestrian-operated signals. In the matter of road junctions the committee did not act up to this wise principle of throwing the onus of judgement upon the driver. It reports that in some cases it may be desirable to require drivers to stop before entering the main (or "major") road, and for this purpose there has been designed a specific sign, a red triangle within a red circle above a plate with the word "HALT." Many members of the committee, including the chairman, dissent from this view, and hold that the use of this sign would be prejudicial to the present and recommended system of warning signals and be a retrograde step. It departs from the principle of informing the driver of the character of the danger ahead and leaving him to adjust his driving accordingly.

The committee is definitely of opinion that light signals are more economical than police for controlling road junctions and that these can alternately stop and release dense streams of traffic at a more rapid rate than a constable could possibly maintain. The evidence given by the British Medical Association is accorded considerable space. It dealt with the risks of the confusion of colour signals and suggested that the red and green lights should be also distinguished by shape—a horizontal bar of red light and a vertical bar of green light. The committee considers that (despite the experience of the railways and shipping) there is a lack of evidence that colour-blind drivers do in fact find difficulty in interpreting light signals either by day or by night. It was clear, in the discussion of the matter with the committee, that the fact that so many cities and countries had already adopted the circular bull's

[1] Report of the Departmental Committee on Traffic Signs. London: H.M. Stationery Office. 1933. (3s. net.)

eyes weighted the scales against any change unless under strong pressure. The committee, however, recommends that signal heads should be banded white and black so as to indicate the position of the lights. It was also pointed out to the committee that risk arose from the confusion of other street lights, illuminated advertisement signs, and even the chemist's red bull's eye, with the signal lights, but no note is made on this point, though the reverse is provided for in the direction that care should be taken when the installation of light signals is under consideration that there is no possibility of confusing these either with navigation lights for the guidance of shipping or persons in charge of craft on inland waterways, or with railway signals. Special shields may here and there be necessary to ensure that light signals are not seen by persons other than those for whom they are intended. It is evident from comments made in the lay press that more will need to be done with regard to the excessive multiplication of illuminated advertisement signs. These may soon become so numerous as to destroy each other's effectiveness ; then, perhaps, traders will wonder if the cost is worth while. The *Times* has called attention to another point omitted from the report: the difficulty of reading lighted signals in broad sunlight.

White lines are considered with much care. The committee concludes that they are of much utility, but it adds that they should be confined to places at which it is clear that they will reduce danger or be of material assistance to traffic. An overuse of white lines in one locality will not only tend to reduce their effectiveness generally, but may give an unwarranted sense of security to drivers in adjoining districts where more restraint in their use has been exercised. The marking of the roadway should be strictly limited to directions ; an order such as " STOP " should never be on the carriageway. The committee has been commendably expeditious in the issue of its report, and the carrying into effect of its recommendations should secure such uniformity in traffic signs as will tend to the better order and safety of the King's Highway.

CANCER RESEARCH

Ten years ago the British Empire Cancer Campaign was launched, its primary objective being the discovery of the cause and cure of the disease. It was not expected, of course, that such an ambitious programme would be realized immediately: the difficulties and complexities of the subject were too well known to the experienced doctors and scientists who constituted the organizing committees. What they set out to do was to build up an organization which would encourage and co-ordinate cancer research throughout the British Empire. How far they have succeeded in this will be seen from the review of the activities of the organization furnished by the tenth annual report of the Campaign.[1] The first thing to do with an annual report is to run quickly through its pages and notice its contents and arrangement. This treatment of subjects in the present volume at once reveals the amazing complexity of the cancer problem. One worker is at it with the chemistry of dibenzanthracene; another is watching successive generations of rats with the contemplative eye of Mendel observing his peas, another is trying the effect of anti-cancer serum on human patients, others are working with radium and *x* rays, others searching for treasure in the dusty files of hospital follow-up systems.

Almost every page of the two hundred in the tenth annual report refers to some new form of activity directed to the advancement of our knowledge of the cause and cure of cancer. There must be many minor pieces of research in cancer which have only been made possible by the support and encouragement of the Cancer Campaign. The first glance through the report, then, is like a peep through the window of a factory. We see many different types of movement and no apparent unifying purpose. This, however, at once becomes obvious if we look more closely at any one of these separate operations. A good one to start with is the work on cancer-producing chemicals. This began with the discovery some sixteen years ago that mice develop cancer when the skin of the back is painted with crude tar. It led to a search for other carcinogenic substances, and concentrated attention on what particular constituent of crude tar could be responsible for this fatal change in the character of cell growth. It seems that the particular chemical constituent of tar responsible is 1:2-benzpyrene, seven grams of which can be extracted from two tons of gas-works pitch. Mice develop cancer more rapidly and more regularly after the application of this chemical in a pure state than after painting with crude tar or any of its other known derivatives. Meanwhile another substance, dibenzanthracene, has been found to have equally powerful carcinogenic properties. This is a synthetic chemical not obtained from tar. It causes carcinoma or sarcoma in several different species of animals besides mice, when applied locally or injected. It is interesting to notice that this substance has a similar molecular structure to benzpyrene, which gives tar its cancer-producing properties. One immediate object of research is the attempt to trace a relationship between human cancer and previous exposure to some such carcinogenic agent. It is possible, for instance, that minute quantities of such chemical substances may be present in materials which are used by human beings for food or clothing, or that similar substances may be formed in our bodies as by-products of activities. This is obviously an encouraging field for research.

Anti-cancer serum which had already proved successful in destroying tumours in mice has now been applied to inoperable human cases. The results are as yet too few for conclusions to be drawn, but they have been sufficiently encouraging to produce " temporary benefit in several of the cases," and to indicate a continuance of research on these lines. A good deal of new work is being done to improve existing methods of treating cancer. The disease presents a different problem in every organ of the body, and whether the treatment be surgical or medical or by radiations, there

[1] British Empire Cancer Campaign, 12, Grosvenor Crescent, S.W.1.

are particular difficulties to be overcome in each different type of tumour. The classification and grading of tumours, the manner of spread of different types of malignant disease, the careful recording of all cases of cancer which have been treated, including the following up of such cases to ascertain their subsequent history, are all very important branches of cancer research. This may appear an unromantic field to till, but it is sure of a useful, if unspectacular, harvest. One thought in conclusion before the report for 1933 is placed on the shelves beside its predecessors. The writers referred to in this document are only the agents of a much larger group of supporters who have given their time or thought or material help to create and further this great organization for the discovery of the cause and prevention of cancer. The success of the Campaign depends on continued support. This was pointed out very cogently by the Duke of York when presiding over the annual general meeting on July 10th. He suggested that in future years an appeal might be made throughout the British Empire on Empire Day to aid the work of the Campaign at home and over-seas. "The final victory over cancer would indeed be a matter for universal rejoicing, and I therefore submit that that day be considered in connexion with our appeal activities."

AETIOLOGY OF INFLUENZA

In recent years the views on the aetiology of influenza have undergone a change. The days have passed when the bacillus isolated by Pfeiffer—known now as *Haemophilus influenzae*—held first place as causal agent, and most people have come to believe that a filterable virus is responsible. There has been some experimental evidence to support this view. Nicolle and Lebailly (1918) and Yamanouchi, Sakakami, and Iwashima (1919) have reported the successful transmission of influenza to human volunteers by means of filtered material; in fact, the Japanese experiments succeeded with a regularity that investigators of biological problems hope for but rarely encounter. Then there were the claims by Olitsky and Gates (1921) and Gordon (1922) to have cultivated filter-passing organisms from cases of influenza, but in neither case were the conditions of cultivation those which have since been found necessary for so many filterable viruses, and the evidence in support of *B. pneumosintes* (Olitsky and Gates) as the causal organism of influenza is not convincing. The last few years have passed without further light being thrown on the problem of the causation of influenza, and without doubt this has been due to the lack of a suitable experimental animal. Man alone seemed to be available for this purpose, and for obvious reasons there has been a reluctance to make use of human volunteers.

Just when the possibility of any further advance seemed rather remote has come the announcement[1] that three investigators at the National Institute for Medical Research, Dr. Wilson Smith, Dr. C. H. Andrewes, and Dr. P. P. Laidlaw, have succeeded in transmitting influenza to ferrets. The whole aspect of the situation has been transformed. Profiting by the recent epidemic to reinvestigate the whole problem, these workers tried to infect a variety of laboratory animals. At first they met with the usual negative results, but, undaunted by this lack of success, they pursued their quest and were rewarded in the end by finding that the ferret was susceptible. Ferrets inoculated by nasal instillation with the filtered throat washings of early cases of influenza went down after a two-day incubation period with fever, nasal discharge, and obvious signs of illness. Not only could the condition be passed from ferret to ferret by filtered suspensions of nasal mucosa, but mere contact sufficed for the transmission of the disease. This entailed the removal of the investigation to the Institute's Farm Laboratories at Mill Hill, where all the machinery of rigid isolation elaborated for the work on distemper could be made use of. Here the work was continued, and Drs. Smith, Andrewes, and Laidlaw have established that a filterable agent is present in the throats of early cases of influenza which is capable of producing disease in ferrets. The material from five out of eight human cases proved virulent; the throat washings from four normal individuals and one with a cold gave negative results. Ferrets which had recovered from an attack proved resistant to reinfection; their serum possessed neutralizing properties for the virus; and, what was more important, the serum from human influenza convalescents, in a high percentage of cases at any rate, was similarly endowed with neutralizing power. This work leaves little doubt that influenza has been transmitted to ferrets and that the prime cause of the disease is a filterable virus.

A short while ago, at the time of an epidemic of influenza in America, Shope (1931) isolated a filterable virus from a disease in pigs known as swine influenza. This virus by itself did not reproduce the natural disease; it gave rise merely to a mild febrile disturbance with little or no obvious symptoms. But when the virus was combined with an influenza bacillus—*Haemophilus influenzae suis*—which was constantly present in the natural disease, the complete clinical picture of swine influenza was obtained. The partnership of these two factors, virus and bacillus, was essential for the production of the disease; but, as Shope showed, it was the virus which was the primary causal agent, for the influenza bacillus alone was quite avirulent. The Hampstead workers have been able to compare Shope's virus with their human strain, and find that they are closely related antigenically. Unlike its behaviour in the pig, Shope's virus produces the complete disease picture in the ferret without the collaboration of the influenza bacillus; the same is true of the human influenza virus. Whether human influenza requires for its production the close partnership between the filterable virus and Pfeiffer's bacillus which pertains in the case of swine influenza only further work will show. Many other problems present themselves for solution, and the medical profession will anxiously await the next advances which this brilliant piece of work has made possible.

THE HUNTERIAN MUSEUM

From the preliminary statement in the annual report on the museum of the Royal College of Surgeons of England it appears that since last October the Conservator, Sir Arthur Keith, has been on leave of absence owing to illness. Happily his health is now in great measure restored, but continued residence in London has been deemed inadvisable, and he has transferred his activities to Downe, although, doubtless, he will take a continued interest in the Hunterian Museum, which had the advantage of his leadership for so many years. Fortunately, a popular and able acting Conservator has been found in Mr. R. H. Burne, the Curator of the Physiological Department, who presents the report for the past year. The museum has also suffered a heavy loss in the death of Mr. C. F. Beadles, the Pathological Curator, whose connexion with the museum dates back to the year 1909, and whose name will always be associated with the War Museum. The report is divided into two parts, the first giving details of the work of the several departments and brief descriptions of the additions made to the museum collections, the second consisting of the reports of the research workers in the laboratories, presented by Dr. G. Scott Williamson. The additions to the museum, nearly four hundred in number, have been placed in Room I, where they will remain for the inspection of visitors until August 4th. They illustrate well the varied activities and interests of the museum, including the subjects of normal and pathological anatomy, both human and comparative, physiology, anthropology, historical pathology, surgical instruments and appliances, and forensic medicine. Among the pathological specimens may be mentioned several illustrating favourable results after excision of carcinoma of the larynx, a remarkable specimen of cirsoid aneurysm of the coronary vessels of the heart, a valuable series illustrating diseases of the gall-bladder, and specimens of endometritis polyposa and "tarry cyst" of the ovary. Conspicuous in the physiological section are the beautiful preparations and injections made by Mr. Burne, particularly those illustrating the ossification of the skeleton in the embryo. Of other additions to the series of human osteology the most important are nine casts of the skeletal remains of early Pleistocene man from the Peking caves. The report of Miss Tildesley, Curator of the Department of Human Osteology, gives evidence of the great value of the anthropological collection to those engaged in biometric inquiry, and of the numerous demands made on her department for reports on excavated specimens from all quarters. The additions to the odontological department consist mainly of specimens illustrating the comparative anatomy and pathology of the subject. They occupy five pages of the report, and their number serves in some degree as a measure of Sir Frank Colyer's determination to bring his collection to perfection; it must now be the finest odontological museum in the world. A striking addition to the museum, placed in review order in Thompson's Historical Section, will arouse the tenth qualified perhaps with some reserve, of thing to do with English history. It consists of two bones through its casts of the skeleton of Queen Berengaria the supply of subject of King Richard Cœur de Lion. A more difficult to carrk has been done during the year the College. Dr. Scott Williamson and Dr. Innes Pearse have continued their studies on the relationship between the pituitary and thyroid functions; Mr. H. J. Burrows has already recorded some of the results of experiments on tissue culture in his Hunterian Lecture, and has other papers ready for publication on that subject; Mr. J. H. Thompson has continued his interesting experiments on the growth-retarding factor of parathyroid extract; Mr. Laurence O'Shaughnessy has already embodied the results of his work in his Hunterian Lecture on the surgery of the oesophagus, and has also been working on various aspects of neurectomy and on the surgery of the thoracic organs; Sir Charles Ballance has been engaged in the study of the Rolandic cortex and the cervical sympathetic, and Mr. Winsbury White on the lymphatic pathways from the genitals and lower urinary tract towards the kidneys, the results of which were set out in his Hunterian Lecture delivered last February.

ASTHMA AND AIR FILTRATION

It is becoming more and more recognized by the clinician that true spasmodic asthma must be sharply differentiated from the crippled lung type as well in treatment as in pathogenesis. The victim of the former, as Bray[1] points out, inherits his liability to anaphylactic phenomena as a Mendelian dominant characteristic; he is the subject of skin affections and exudations of various mucous membranes which, show, with the blood, a high percentage of eosinophils. Conjecture is still rife as to whether the initial change is or is not an urticaria of the bronchial mucosa leading to the secondary spasm and ultimate thickening of the muscle of the "respiratory bronchiole" with which the pathologist is familiar. The secondary spasm and thickening in the second type may arise from any lung damage, and appears (Graham) to be related to stenotic processes in the larger or smaller bronchi. It is well seen in the "asthma" of pulmonary tuberculosis, in bronchiectasis, and in the pneumoconioses. The exciting cause of an attack is related to bacterial infection of the upper respiratory tract and not to foreign protein *per se*. Interesting confirmation of this distinction occurs in two articles dealing with the treatment of hay fever and pollen asthma by air filtration by Gay[2] of Baltimore and Nelson[3] and his fellow-workers in Chicago. The relief of the current asthmatic attack of the pollen type with the patient in a chamber of filtered air is as striking as the complete failure to improve the "control" cases of bacterial asthmatic spasm. Machines admitting of adjustment of temperature and humidity were attached to one or two hospital wards containing from four to eight beds. Pollen counts on greased slides placed in the ward and adjoining passages before and after filtration showed differences from as much as 600 grains per cubic yard for the outdoor "settling" count to under 10 grains in the moving air of the large ward. The efficiency of the filter (preferably 4-ply cellulose) depended directly upon frequent changing; other disturbing factors are detailed. The conclusions reached were, in effect, that the hay fever patients were immediately benefited. The pollen asthmatics, if confined long enough (a factor varying from twenty-four hours to

[1] Bray, George W.: *Arch. Dis. in Child.*, 1930, v, 237.
[2] Gay, Leslie N.: *Journ. Amer. Med. Assoc.*, 1933, xviii, 1382.
[3] Nelson, Tell, Rappaport, B. Z., and Welker, W. H.: Ibid., 1933, xviii, 1385.

ten days), were in time relieved of their subjective symptoms, although after forty-eight hours the objective signs of asthma had disappeared in only five. The tolerance of patients to excursions into the outside atmosphere varied from one-half to twelve hours in the twenty-four, and might differ for the same patient on successive days, though it was chiefly determined by the severity of the asthma. Confinement for a time in filtered air before the seasonal onset of the asthma will not prevent its usual occurrence. When patients were discharged from the filtered chamber the asthma invariably returned with equal severity. For economic reasons, then, only those patients who could afford to install apparatus in their own homes are likely to derive permanent benefit. For hospitals, such a room might be of use for serious cases of status asthmaticus, or for a short period in which it was intended to carry out some operative procedure. Confirmation also emerged of the general feeling that weather conditions and other factors besides pollen concentration have a certain effect in precipitating an attack in pollen-sensitive patients: thus, cooling the filtered air often aggravated the asthma because of an increase in relative humidity.

A CHARLATAN EXAMINED

The widespread activities of charlatans, quacks, latter-day sorcerers, and the like on the Continent has led to the publication by an International Committee in Brussels of a review[1] which purports to concentrate attention on these practices in general, on any case which comes before the Courts, and on any scientific examination of claims made by such people. It may be doubted, however, if any practical purpose is served by such a publication. The medical man has no means of combating the sale of patent medicines and nostrums other than by publishing their composition or action (if any), and the influence of the irregular practitioner is even more difficult to deal with, as it may occasionally be beneficial—as in those cases of imagined disease or neurosis, in which sympathetic handling by a strong personality is indicated. Patients of this kind easily fall victims to quacks when medical treatment applied on orthodox lines fails, for it is in the nature of many men and women to show preference for the mysterious and incomprehensible. Great prominence is given in the review to a clear demonstration recently undertaken by Bessemans to prove that the diagnoses of a *sourcier*, who used the familiar handwriting-planchette-pendulum nonsense, bore no relation to the conditions from which the patients were suffering, and were, in fact, complete rubbish. A side-by-side comparison of the medical and quack diagnosis, in ten cases, makes amusing reading. A sample is given below, the sorcerer's comments appearing in parentheses: Case 1—Healing fracture of right elbow (heart and nerve disease) ; Case 2—Fracture of right clavicle (disease of the liver) ; Case 5—Varicose ulcer of left leg (ear disease) ; Case 6—Impetigo (" kidneys and bladder ") ; Case 7—Eczema (disease of intestines) ; Case 10—Anthrax of right shoulder (eye disease, intestinal inflammation, pain in left leg under the knee, " stomach, pyloric region "). It is improbable that such a demonstration will exert any influence on the simple-minded patients of the quack, but that seems all the more reason for the law to prohibit his practices under severe penalties.

MAN AND MACHINE

A most important theme, and a very effective presentation of it, will be found in a pamphlet by Dr. L. P. Lockhart, entitled " Mind and the Machine." It is a reprint of a lecture recently delivered under the auspices of the League of Industry.[1] The theme is the machine, not " as the destroyer of the finer and more individualistic aspects of human life," but " as an aid to fuller human development," and the need and difficulty of making appropriate and sufficiently rapid mental adjustments to this end. To plan and control material progress is not enough in itself to ensure human advancement. It is necessary to consider and arrange every aspect of life, and not one side of it or a mere selection only. " We must not only plan and organize our material advantages, but we must also apply scientific investigation to the vital question of mental adaptation." To remember that man is governed quite as much by instinct and emotion as by intelligence and reason is essential for this purpose, and the large extent to which suggestion replaces reasoned argument must never be forgotten. Incidentally, we observe that Dr. Lockhart defines " suggestion " as " a means of inculcating ideas merely by the manner of stating them without offering any logical support for the conviction enjoined." Two points are clearly brought out and strongly enforced: the need for biological knowledge, and especially for a biological outlook, for every citizen, particularly for those who hold any post of responsibility in government or in industry ; and the need for developing outside the bread-winning function other satisfactions which will not only maintain a balanced mental life, but may also help to consume some of the fruits of machine activity in mass production.

" Once we had psychological satisfaction in the midst of material scarcity ; now the problem is completely inverted . . . If employment to-day cannot give to man the full satisfaction that came to the older craftsman and to the small independent trader then merely to offer work is not to complete the mental life of man but rather to leave it still unsatisfied. . . . In all forms of education we should therefore strive, not indeed to turn out masses of half-baked technical biologists, but we should give to every boy and girl that degree of understanding of living processes as shall enable them to appreciate the evidence on vital problems as it comes to them. To say that biology regarded from this standpoint is not ' cultural ' is mere pedantry, for what can be of greater cultural value than to have insight into living phenomena without which all history, all literature, and in fact the whole of life is meaningless? "

Dr. Lockhart has on previous occasions, at Annual Meetings of the British Medical Association and elsewhere, made valuable pronouncements on the psychological aspect of problems of social welfare and industry.

MEDICAL EDUCATION: A CANADIAN STUDENT'S VIEWS

A series of articles has appeared in the *Canadian Medical Association Journal* during this year on the subject of medical education, and in the June number is one by a medical student, Mr. A. C. Corcoran, B.A. Mr. Corcoran remarks that a medical student's criticism is apt to be hasty and directed to details, but his article is free from both of these alleged tendencies, and is a considered statement written after conference

[1] League of Industry, St. Stephen's House, Westminster, S.W.1. (2d post free.)

with contemporaries in his own school of Montreal and elsewhere. The article contains criticism and suggestion. The criticism may be summarized as follows: the view is expressed that the prospective medical student's secondary education is "not good enough"; that standardization by the various universities of the teaching in chemistry, physics, and biology is needed; that there is not always the necessary continuity between the teaching of the pre-clinical period and the clinical subjects; that clinical education should be based upon learning how a patient should be approached and his symptoms and signs of disease recognized, rather than upon efforts at hasty diagnosis. This summary by no means exhausts the points raised in the article, which is well worth reading by all concerned. It adds to the evidence already to hand that medical training is in need of review *as a whole*; it should be given to the student as a whole—it is too often presented to him as a collection of disconnected parts, and the lack of connexion confuses and wearies him. To overcome the latter tendency in any particular school authority is required, and that is not always forthcoming. The authority needed must be fully alive to the purpose and end of training, and at the same time accept the fact that much instruction which has no direct and obvious application to practice is needed if the student is to be capable of forming judgements which are his own. It is only by the teachers of a school that the necessary co-ordination can be achieved—no external authority can achieve it; but external authority, if it devoted sufficient time and care to the framing of recommendations might gain the confidence of the schools and influence opinion in the right direction: unless it were successful in earning the confidence of the schools it would achieve nothing. The sequence in a curriculum should be such that the student is aware of it himself; to anyone who will take the trouble to scrutinize a series of examination papers the want of ordered sequence will be apparent in many instances; the questions of an examination paper are a fair index of the teaching. One matter to which Mr. Corcoran refers, and which is sometimes forgotten when graduation has become a distant memory, is that the mental capacity of the medical student is subject to the same limitations as that of the ordinary human being, and that he should be given not only facts but time and even leisure to digest them. A temperate and reasoned expression of opinion such as Mr. Corcoran has written is welcome; it contrasts favourably with some other critical articles on the same subject published lately.

The inaugural ceremony in connexion with the third International Paediatric Congress will take place on Thursday, July 20th, in the Great Hall of B.M.A. House, Tavistock Square, W.C., at 10 a.m. The Duke of York, accompanied by the Duchess, has consented to open the congress and make a speech of welcome. In view of the attendance of Their Royal Highnesses members of the congress are asked to be in their places not later than 9.55 a.m.

In our correspondence columns this week appears an influentially signed letter from Bristol announcing a proposed memorial to the late Dr. Carey Coombs, which we are sure will meet with a sympathetic response in places far beyond his immediate field of work.

MEDICAL PROBLEMS OF CONTRACEPTION

CONFERENCE IN LONDON

A medical conference on contraception was held at British Medical Association House on Saturday, July 8th, under the joint auspices of the National Birth Control Association and the Birth Control Investigation Committee. The discussions, each occupying one session, were concerned with recent research on temporary hormonic sterilization, information on birth control by public health authorities, chemical spermicides, and birth control instruction in general practice.

TEMPORARY HORMONIC STERILIZATION

Professor JULIAN HUXLEY, who presided at this session, said that in the view of the Birth Control Investigation Committee temporary hormonic sterilization held great promise as a method of birth control. The present mechanical methods were near the limit of their efficiency, and even chemical methods, though capable of considerable improvement, had and would always have certain inherent disadvantages. If, as was perfectly possible, a satisfactory means of inducing temporary hormonic sterility could be found which would be operative over a definite period, say for one menstrual cycle as a result of a single injection, many practical and aesthetic objections to contraception would be surmounted. Indeed, we should look back on our present methods as the motorist looked back on the bicycle age, or as the modern book trade might look back on clay tablets.

Mr. C. W. BELLERBY said that the practical application of hormonic methods was contingent on the discovery of processes for synthesizing the substances concerned or on finding cheap methods of preparing them from existing sources of supply. The main obstacles to progress along these lines had been, first, the complete side-tracking of work on the anterior pituitary hormones by the discovery in the urine of pregnancy of substances with apparently identical properties; and, secondly, the assumption by most workers on the subject that these substances were actually elaborated by the anterior pituitary lobe. No evidence had in fact been produced in support of this contention, which accordingly invalidated work on pregnancy urine which purported to throw light on the chemical and physiological properties of anterior pituitary hormones. The differences that had been found between crystalline oestrin prepared from urine and oestrin extracted from ovary served further to underline this distinction. It was now generally accepted that the periodic alternation of fertility and infertility in animals was controlled by the anterior lobe, and it therefore seemed likely that complete control over the duration of the fertility or infertility period might be obtained by isolating and administering the factor or factors concerned. Work had been held up, however, by lack of a suitable test animal; but the speaker, using the African clawed toad, had devised a reliable quantitative method of assaying the hormone and had progressed considerably in his studies on the chemistry of the anterior lobe. He had found it possible, moreover, to prepare extracts of the gland having a far greater activity than any hitherto reported. He had found no support for the view that more than one pituitary hormone was concerned in the regulation of the ovarian cycle. This work had been carried out under grant from the Birth Control Investigation Committee.

An informal discussion followed, in which Dr. C. P. BLACKER, Dr. CECIL VOGE, and Professor HUXLEY took part.

CONTRACEPTION AND PUBLIC HEALTH SERVICES

In her introductory remarks on this subject the chairman, Dr. HELENA WRIGHT, reminded the conference that under the Ministry of Health Act, 1918, local authorities wishing to give birth control advice could do so on gynaecological grounds only, and even then only in the case of pregnant married women. But the Act was by

no means uniformly interpreted and in different areas there existed vastly different conceptions of the meaning that could justly be applied to the term medical grounds"

Mrs FRANCIS IVENS KNOWLES, surgeon in charge of the Women's Clinic, Walthamstow, said that this clinic had been set up under Section 131 of the Public Health Act to conduct ante natal and post natal consultations, deal with gynaecological conditions, and advise sick persons on contraceptive methods In this last function it was limited exclusively to women who attended for advice or treatment in connexion with gynaecological disorders, or for whom pregnancy was undesirable on strictly medical grounds During the year 1932 the patients needing contraceptive advice formed 17 per cent of the total attendance In some of these, dread of another pregnancy had set up a 'fear neurosis,' which had been intensified by the use of such birth control methods as coitus interruptus, or by inability to sleep through the noise made by ailing and nervous children Others were suffering from debility brought about by frequent child bearing, this condition sometimes being intensified by the anaemia of lactation, the presence of prolapse from untreated perineal tears, and even by too early a return to the routine of household work For many such women the Mensinga type of pessary was useless without preliminary operation The speaker drew attention to the dangers that were associated with the use of septic marine sponges, there were disadvantages, too, in certain foam preparations, for these in some cases produced local pain and irritation Discussing the morbidity due to excessive child bearing, Mrs Ivens Knowles said that routine examinations conducted at the clinic revealed the presence in multiparous women of cervical lacerations which might be the precursors of malignant disease In 100 cases of carcinoma of the cervix which had been under her care the average fertility rate of the patients worked out at 6 5, twenty three of the patients having had more than twelve pregnancies, and one patient twenty pregnancies In conclusion, she suggested that the establishment of women's clinics in populous districts would do much to alleviate the sufferings of overburdened mothers, and enable them to regain their health and vitality Such clinics should be organized in close co operation with the practitioners of the district, be staffed by experienced gynaecologists and obstetricians, and be connected with fully equipped hospitals

Dr A G M SEVERN medical officer of health, Pontypridd, gave an account of the establishment of the first birth control clinic in South Wales and the experience gained since its inception In this area large families were common, and for many years the maternal mortality had been well above the average for the rest of the Kingdom For these reasons a voluntary organization had established a birth control clinic in Pontypridd in 1930, and the local authorities had permitted it to use the premises of the ante natal clinic for its sessions on condition that it bore all capital and maintenance expenses This clinic was not bound by any of the restrictions imposed by the Ministry of Health, and gave advice on economic as well as on health grounds The following year, however, the local authority, having considered the Ministry's memorandum, decided to take over the clinic as part of its maternity and child welfare service, with the result that the conditions imposed by Circular 153 became operative and patients were no longer accepted on other than health grounds The example of Pontypridd had led to a demand for similar clinics in the area, and five local authorities in South Wales had now established clinics of their own Turning to a consideration of the medical conditions on account of which the women had been referred to the clinic, Dr Severn gave an analysis of the last 100 case cards, which showed that eighteen were suffering from debility brought about by excessive child bearing, fourteen were tuberculous, thirteen suffering from renal disease, ten from anaemia, nine each from epilepsy and heart disease, five from pelvic deformity, and four from debility due to miscarriage Previous abnormal labour, severe neurasthenia, hip disease, asthma, paralysis, goitre, and uterine prolapse accounted for the rest In a few cases early disease of the uterus had been discovered and been referred for treatment to the Cardiff Royal Infirmary It was noteworthy that several women had attended for advice on sterility An examination of the records showed that the clinic was not reaching the most ignorant and physically unfit members of society the majority of the women who came for advice belonged to superior working class stocks It seemed as though there was a need for even simpler contraceptive methods than those recommended by the clinics, and perhaps in some cases nothing short of sterilization would be effective Dr Severn suggested that the results of the Pontypridd experiment demonstrated that the best way of starting birth control clinics in areas where these were likely to meet with opposition was for voluntary organizations to make a start and then convince the local authorities that they met a genuine demand Town councils were disinclined to experiment with public money but they could hardly fail to appreciate the value of a going concern

Dr LILIAS JEFFRIES describing the work of a clinic conducted by the Brighton Town Council under the terms of the Ministry of Health's memorandum said that patients were sent exclusively by the municipal health services—for instance, by the tuberculosis officer, the mental hospital, and the ante natal clinic—with a definite statement that they were medically unfit for further pregnancy General practitioners knew about the clinic, but rarely used it In most cases the appliance recommended was the Mensinga pessary, though the size —65 in the average case—was smaller than was generally favoured The best method, according to the speaker, was by the use of the sheath together with a contraceptive jelly or tablet, but she agreed that some couples disliked it on aesthetic grounds, and that many women preferred methods that kept the prevention of pregnancy within their own control It was one of the contributions of birth control clinics to the public health that they were instrumental in discovering pelvic lesions and putting women in the way of proper treatment They could, however, successfully serve this purpose only when they were conducted by qualified practitioners and the speaker deprecated the practice of placing such a responsibility upon nurses and midwives She urged that the powers of clinics should be extended to giving advice on eugenic and economic grounds, and, as an example of progressive action, she instanced a recent decision by the East Sussex County Council that she should see and help women patients of child bearing age when they were to be discharged from the mental hospital

Dr C KILLICK MILLARD said that in Leicester they had found themselves much hampered by the terms of the Ministry's memorandum, but after an interview with an official of the Ministry he concluded that 'gynaecological" was a fairly elastic term Dr VERNE BORLAND said that the Minister of Health had recently congratulated the nation on its low rate of infant mortality but maternal mortality remained high, largely owing to the prevalence of abortion as a substitute for birth control Dr C P BLACKER agreed that extended powers were needed for municipal clinics, and stated that a group of M P's had been formed to secure this end

CHEMICAL SPERMICIDES

Lord HORDER, who presided over this and the next discussion, said that the programme of the conference struck a nice balance between the theory and the practice of the subject In Dr John R Baker's absence he asked Dr Blacker to read an account of the investigations on chemical spermicides that had been conducted (under grant from the Birth Control Investigation Committee) by Dr Baker and his co-workers at the Department of Zoology, Oxford

Dr Baker had designed a new laboratory test of the spermicidal power of suppositories which by giving a much closer correspondence with clinical results than his previous test was able to provide information of value

to clinical workers. In this test one suppository was mixed with 2.5 c.cm. of a fluid representing that of the vagina, and, when the suppository had disintegrated, this fluid was mixed with 5 c.cm. of an artificial semen consisting of cavy sperms suspended in albumen-saline—a fluid consisting of beaten egg-white (23 volumes) and 0.9 per cent. sodium chloride (7 volumes). The sperms were examined microscopically five minutes later, and it had been found that cavy sperms in this suspension behaved to the most diverse spermicides almost like human sperms in human semen. Taking the concentration of one suppository to 2.5 c.cm. of artificial vaginal fluid and 5 c.cm. of artificial semen as the standard—called S—suppositories were tested at S, S/2, S/4, etc., until the lowest effective concentration (namely, the lowest concentration which killed every sperm in two consecutive experiments) was found. With suppositories that relied on their acidity to immobilize sperms a suspension fluid had to be used with the same alkaline reserve as that of human semen, Dr. Baker having devised for this purpose a mixture of beaten egg-white (16 volumes) and a 6 per cent. solution of $Na_2HPO_4.12H_2O$ (14 volumes). Acidity destroyed the spermicidal powers of some spermicides, and in some cases the vaginal fluid might be acid enough to acidify the semen, but not to immobilize the sperms. When there was reason to suspect such sensitivity to acid in a suppository it was necessary to use an artificial vaginal fluid which would just acidify the sperm suspension in albumen-saline. Such an acid vaginal fluid could be prepared by mixing a 2.7 per cent. solution in water of lactic acid (31 volumes) with 0.9 per cent. sodium chloride (69 volumes). Soap was recommended as a spermicide, though the presence of protein reduced its effectiveness. One-tenth of a gram of sodium oleate had a lower effective concentration than any of the suppositories tested, and it was insensitive to acidity.

Lord HORDER said that Dr. Baker's paper, by illustrating the complexity of the problems within its field and the difficulties that had to be met in coping with them, showed how important it was that such a body as the National Birth Control Association should keep in touch with those aspects of contraception that came within the province of the Birth Control Investigation Committee. Replying to questions by Dr. DUNLOP, Mrs. HODSON, Dr. KILLICK MILLARD, Mrs. SPRING-RICE, Dr. VOGE, and Dr. FISHER, Dr. BLACKER said that though in theory direct ejaculation of semen into the uterus was a possibility, in practice there was little evidence of its occurrence. The suggestion that spermicides might damage without killing spermatozoa and so cause the production of defective offspring seemed to him groundless, but the Investigation Committee would study this question when work designed to discover the most effective spermicide had been completed. Soap-suds were harmless as well as effective spermicides, but solid soap would be harmful. As for the vehicle, Dr. Baker favoured cocoa butter and fatty substances, but it was important to discover substances that would serve this end in hot climates. The chief disadvantage of jellies was their cost, and of the use of sponges in olive oil that they had to be boiled for five minutes after coition.

Dr. H. M. CARLETON followed with a paper on the after-effects of inserting Gräfenberg rings in the body of the uterus. During the past year two rhesus monkeys had had silver rings inserted for seven and eight months respectively. In both the endometrium was found to be flattened at its points of contact with the ring, and in one the uterine glands had atrophied. At the necropsy of one of the subjects it was found, furthermore, that the endometrium had turned dark grey and the ring was blackened. Histological examination showed a large number of dark granules, mostly extracellular, lying below this endometrium. Dr. H. J. Phelps and Dr. John Phelps had demonstrated that the pigmentation was due to the deposition of a silver salt. These results confirmed earlier investigations made with the rabbit as test animal; and the further observation by Dr. Helena Wright that the silver ring was sometimes blackened in the human female suggested that deposition of silver granules also occurred in the human uterus. The pathological import of the deposition of so insoluble a compound was possibly very small; far more important, however, was the fact that the chemically changed ring became very brittle and liable to fragmentation in the uterine cavity. When due weight was given to the fact that prolonged irritation favoured the development of cancer, it could hardly be doubted that there was a potential danger in introducing into the uterine cavity a foreign body which was apt to undergo both chemical changes and physical fragmentation. In reply to discussion (in which Dr. DAVIDSON took part) Dr. Carleton said that he would think twice before inserting either a gold or a silver ring into a human uterus; and Lord Horder added that a satisfactory solution of the practical problems of contraception could hardly be in the production of prolonged irritation of the uterine cavity.

BIRTH CONTROL IN GENERAL PRACTICE

Dr. E. F. GRIFFITH, analysing his experience as a general practitioner who had taught birth control to about 500 patients in the past two years, said that in spite of the harmfulness and inefficiency of the methods commonly in use, some 90 per cent. of married couples adopted them for lack of better knowledge. In his practice he had found it possible to obtain nearly 100 per cent. of successes, and in the course of the necessary routine examination had been able at the same time to discover gynaecological disorders. He regarded the inculcation of the idea that births should be spaced and that women should have scientific advice on contraception as an essential part of medical practice, and pleaded for a fuller sex education of the general public.

Dr. JOAN MALLESON said that in dealing with women patients, and as a way of gaining their confidence, she made a practice of herself introducing the subject of birth control even when she was being consulted on quite other matters. She was able to endorse from her experience all that had been said about the effects on the nervous system of prolonged addiction to coitus interruptus.

In the course of the discussion a number of speakers stressed the need for instructing men patients in the best way of using sheaths.

THE HARVEY MEMORIAL TOWER

FOUNDATION STONE LAID BY LORD DAWSON

In connexion with the rebuilding of the tower of Hempstead Church, near Saffron Walden, as a memorial to William Harvey,[1] an interesting and largely attended ceremony took place on July 7th, when the foundation stone was laid by Lord Dawson of Penn, President of the Royal College of Physicians of London and of the British Medical Association. Among those present were the following:

Sir John Rose Bradford (chairman of the Harvey Memorial Committee), Mr. A. W. Ruggles-Brise (treasurer), and Dr. Arnold Stott (joint honorary secretary of the committee); Lord Horder, Dr. G. F. Still, Dr. R. A. Young, Dr. H. Morley Fletcher, Dr. Sidney Phillips, Dr. Arnold Chaplin; Sir Raymond Crawfurd and Dr. R. O. Moon (representing the Royal College of Physicians); Professor W. Langdon Brown (University of Cambridge), Sir Ewen Maclean (Vice-president of the British Medical Association), Sir D'Arcy Power, Dr. Herbert Spencer, Sir Percival Horton-Smith Hartley, Dr. W. S. A. Griffith; Lieut.-Colonel E. L. Gowland, Dr. G. de Bec Turtle, and Professor Tom Hare (representing the Harveian Society of London); Dr. N. G. Horner (Editor of the *British Medical Journal*), Dr. Michael Foster, Dr. Julius Burnford, and Dr. Ivor J. Davies.

[1] See Sir John Rose Bradford's article, with architect's drawing of restored tower, *British Medical Journal*, July 1st (p. 28).

DEDICATORY ADDRESSES

The occasion was one of great local as well as medical interest, and large numbers of people from the villages for miles around were in the congregation Following a short service conducted by the Right Rev T A CHAPMAN, D D , Bishop of Colchester, Lord DAWSON OF PENN spoke as follows before laying the stone

" The pleasure falls to me first of expressing gratitude to Sir John Rose Bradford, Dr Stott, and Dr Spencer, and, through them, to the many subscribers who have made the commencement of this work possible I should also like to express our appreciation of the enthusiasm of the Rev T P Conyers Barker (vicar of Hempstead), without which this venture could not have come to fruition From William Harvey's discovery there has grown a mighty tree of knowledge, fruitful of blessings to the world His vision, his patient search, penetrated the darkness of centuries of error He had to his hand no new aids, no new methods From within or through himself came the new spirit which found truth and set it forth No darkness can be so great as that of established authority Time gives it the acceptance and the sanction of truth To attack it becomes first an impiety and then an offence During centuries the influence of Galen was paramount, so paramount as to forbid thought, and thus the lamp delivered from the ancients became extinguished Harvey unfolded discovery by his convincing directness and restraint It took but a few pages to refute centuries of tradition and error Despite ridicule, disparagement, and even damage, he implanted the new knowledge with courageous yet courteous insistence He preached that Nature must be pursued through assured, even though they be devious, paths, until the citadel of truth is reached, ' and, saith he, ' in such pursuits it is sweet not merely to toil but to become weary ' There belongs to Harvey a rare distinction, which distinguishes him from most great men who have been makers of epochs, in that there has come down knowledge to us not only of his discovery, but of the man himself Though he be dead, yet he speaketh The spirit of his teaching, his inspiration, his sense of friendship, are still living forces within the profession of medicine That leads me to suggest that this ceremony to day, in which we are all taking part, is not only a memorial It is more , it is a fulfilment of a desire, even a piety, to preserve in men's minds associations of his life and pilgrimage, and it does good to our souls to feel that Harvey is linked with this village, its soil, its landscape, its life, and its worship "

Lord Dawson then laid the stone, saying

In the faith of Jesus Christ, we place the foundation stone of this tower which is being raised to the glory of God and in memory of William Harvey renowned physician and benefactor of humanity in the name of God the Father God the Son, and God the Holy Ghost "

After some prayers, the BISHOP OF COLCHESTER expressed the regret of the bishop of the diocese, the Bishop of Chelmsford, at his inability to be present owing to a long standing engagement The Church of St Andrew, Hempstead (Dr Chapman continued), was full of historical interest as an example of early Gothic It was chiefly fourteenth century in date In 1882 the tower fell, doing much damage to the body of the church The appearance of the church after this catastrophe was deplorable in the extreme, the churchyard covered with debris, among it the fallen bells In 1887 the church, with the exception of the tower, chancel, and Harvey Chapel, was rebuilt In 1883 Harvey's coffin had been removed from the vault and placed in a handsome sarcophagus formed of a single block of Carrara marble, the work being undertaken at the expense of the Royal College of Physicians The project for the rebuilding of the tower was formulated ten years ago, and £3,000 had been raised—a praiseworthy achievement , but the amount was not enough to restore the tower to its full height, and the rebuilding of the ringing room and the belfry must be postponed until a further £2 000 was forthcoming

Of William Harvey the Bishop said that his name was on the scroll of the world's greatest benefactors " *Palmam qui meruit ferat* " This handsome memorial gift to Hempstead Church was much appreciated by the parishioners and by all who loved the ancient building He also paid a tribute to the medical profession, and trusted that there might never be wanting in the land those who gladly used heart and brain in the service of their fellow creatures Finally he prayed divine blessing upon the devoted vicar, who for the past twelve years had given himself heart and soul to this notable effort

The hymn " The Church's one foundation was then sung, and after more prayers the simple and moving ceremony concluded Tea was afterwards served in the vicarage garden

RADIUM "BEAM THERAPY" RESEARCH

Following upon the recent report of the conference on the radium " bomb, ' we are able to announce to day an important development in facilities for research in this country on massive radiation A five gram unit of the element is to be loaned for this purpose, and the research is to be controlled by a governing body representative of medicine and physical science

It will be recalled that when the Radium Commission decided to withdraw and dismantle the four gram " bomb " used for massive radiation at Westminster Hospital some doubts were expressed as to the soundness of the decision, and in any case it was widely felt to be a pity that research on a very large unit should no longer be possible A conference, called together by the Presidents of the two Royal Colleges, was thereupon set up to consider the subject It arrived at the opinion that the decision of the Radium Commission was sound, though this finding was without prejudice to the question of the therapeutic value of four gram or even larger radium aggregations An expert committee was appointed by the conference to consider the scientific case for mass radiation, its advantages and dangers, and from the report of that committee (published in the *British Medical Journal* of January 7th last) it is clear that there is a field of usefulness for massive radium units, given adequate equipment, personnel, and clinical opportunity The report stated " We adopt the view of our committee that it is desirable that a radium unit of not less than five grams of radium element should be established '

This pronouncement, backed as it was by an important body of medical and scientific opinion, led to further activity The initiative was taken by Professor J C M Lellan, F R S , lately professor of physics at Toronto, and a member of the expert committee of the conference, who, with Mr H S Souttar, had specially visited on behalf of the conference the radium institutes of Paris and Stockholm, where large units—respectively four gram and three gram—have been used for the distance therapy of cancer cases by Professors Regaud and Forssell

The Union Miniere du Haut Katanga made a tentative offer of co operation if suitable conditions could be established for facilitating and controlling research The outcome is that the research on what will in the future be termed ' beam therapy (the misleading term bomb having been dropped by something like common consent) is to be organized and sponsored by a representative body of seven members—namely the President of the Royal Society (Sir Frederick Gowland Hopkins who will act as chairman the Presidents of the Royal College of Physicians of London and of the Royal College of Surgeons

of England (Lord Dawson and Sir Holburt Waring), who will be joint vice-chairmen; Mr. Wilfred Trotter, representing the Medical Research Council; Sir George Blacker, representing the Radium Institute; Lord Rutherford, representing the Department of Scientific and Industrial Research; and Professor Arthur Hall of Sheffield, representing the Radium Commission.

Two meetings of this governing body have already been held, the second one at the Radium Institute on Tuesday of this week, when certain proposals took definite shape. It was decided that an Executive Research Committee should be set up, of which Professor M'Lellan should be chairman. The members of this committee will include two clinicians, together with a technical expert in Mr. Geoffrey Pearce, who also happens to be the representative in this country of the Belgian corporation. Another physicist will probably be added, together with two medical men, to carry out the research.

It has also been arranged that the location for the research shall be the London Radium Institute in Ridinghouse Street, Portland Place. The Institute has generously placed the whole of the accommodation necessary for the research at the disposal of the governing body.

These conditions as to effective control and adequate location having been fulfilled, M. Lechien, director of the Belgian organization, has agreed to loan at least five grams of radium, and if necessary at a later date a further five grams, for the purposes of "beam therapy." The loan is free of cost, except for insurance. The Union Minière is a commercial organization, but it is naturally interested in the progress of knowledge respecting radium and its properties, and with that in view it has agreed to make the loan for conducting research in London on mass radiation. We understand that the period provisionally fixed for the loan is two years.

The work before the Radium Beam Therapy Research will be to endeavour to discover how far the present limited field of operation for a massive radium unit in the treatment of cancer may be extended by co-ordinated clinical, experimental, and physical research. This announcement will be welcomed by workers on the non-medical as well as on the medical side, for it is known that some deplored the subdivision of the Westminster "bomb," and hoped that at some future date it might be reassembled. For a result which will place London in a line with Continental radium centres in this path of inquiry thanks are due to Professor M'Lellan for his initiative in the matter, to the Belgian corporation for the generous loan of the element, to the Radium Institute for the provision of facilities, and to the Prophet Trust and to the Royal College of Surgeons for the promise of financial assistance.

A quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on July 5th, when Dr. W. H. Kelson, vice-president, took the chair. The following half-yearly grants to widows and orphans were voted: from the ordinary funds £1,430, from the Brickwell fund £600, and as special grants £129 18s., making a total of £2,159 18s. At the present time there are fifty-two widows and five orphans in receipt of relief. The death was reported of a widow who came on the funds in 1904 and had received in relief £2,100; her late husband had paid in subscriptions £52 10s. A widow of a member recently dead applied for relief, and she was voted £50 per annum from the ordinary funds and £25 per annum from the Brickwell Fund. Membership is open to any registered medical man who at the time of election is residing within a 20-mile radius of Charing Cross. Relief is only made to the necessitous widows and orphans of deceased members of the society. Full particulars may be obtained from the secretary at the offices, 11, Chandos Street, Cavendish Square, W.1.

Scotland

Research by General Practitioners

The forms for the investigation into valvular heart disease (including treatment) to be based upon data furnished by insurance practitioners have now been issued. They have been drawn up by a Committee on Medical Investigations, comprising representatives of the medical staff of the Department of Health for Scotland and of the Scottish Committee of the British Medical Association, which was set up on the recommendation of the Department's Scientific Advisory Committee. The main objects of the present inquiry are: (1) a review of the various methods of treatment in use in general practice; (2) a comparison of the effects of such treatment in various cardiac conditions; and (3) a survey of the incidence and of the relations of the symptoms and signs found to be present. The recording of particulars on this form (M.R.3) commenced as from July 1st, and will be continued for a year, or such period as the Department may determine. The chief problem of the committee was to frame a questionary in a form which would be at once simple for the practitioner and convenient for subsequent analysis and grouping. The signs and symptoms concerning which information is desired are mainly those associated with cardiac decompensation, and these are considered to be the minimum essential data from which a comprehensive view can be obtained of the clinical condition of the patient at the onset of treatment and of the developments which take place during treatment. The form itself is neat and attractive. Information is requested on some twenty symptoms and signs, and the practitioner can record their presence or absence, on each examination, by a plus or minus symbol. Space is given for the record of examinations upon eight occasions, and, in general, the practitioner will not require to record a longer series, although, if he desires to do so, a "continuation sheet" is supplied. In regard to treatment information is sought on the general character of diet, the exercise prescribed, and the medicinal treatment by drugs intended for direct action upon the heart or for the treatment of symptoms. Brief answers to these questions can be given under the headings "drug employed," "preparation," "dose," and "frequency of administration." The last page of the form is left blank for any remarks that the practitioner may desire to make, including notes on other clinical or pathological data. It has been found by trial in several cases that the whole series of observations necessary to complete the record of one examination can be entered in approximately three minutes. The form, apart from its usefulness in relation to the general inquiry, might also be used by the practitioner as a valuable record for his own subsequent information.

Health of Edinburgh

The annual report presented by Dr. John Guy, medical officer of health for Edinburgh, to the Public Health Committee of the corporation refers to several developments of medical interest. The population of the city was estimated at 447,800, an increase of 4,758 as compared with the census population in 1931. During the year there were 6,960 births, including 3,537 males and 3,423 females, giving a birth rate of 15.5 per 1,000, the lowest recorded for the city except for 1917-18. The infant mortality rate was 73 per 1,000 births as against 69 per 1,000 in 1931, and the death rate was 13.5 per 1,000 as compared with the average for the last ten years of 13.9. Deaths from pulmonary tuberculosis

numbered 313, and for the first time in the history of the city there was one ward (Colinton) in which no death occurred from this cause. The city was comparatively free from infectious disease, except for an extensive outbreak of measles in the earlier part of the year, which severely taxed the hospital accommodation. The most noteworthy feature of the year's work was the reorganization of the municipal general hospitals. These are now named the Western, the Northern, and the Eastern General Hospitals, and an attempt is being made to classify patients so that the more acute cases, or cases requiring operation, will be sent to the Western, while the Northern will be reserved for cases of a subacute nature, and the Eastern for chronic cases. The organization and staffing of these hospitals will provide some 900 beds for teaching purposes, and, although many of the cases are chronic, they present a valuable field for medical training and research in regard to senile and bed-ridden persons. With regard to mental health services, an important feature of the year's work was the extension of Gogarburn certified institution, where the number on the register was doubled by the addition of two pavilions, and where the total population at the end of the year was 313. Attention is drawn in the report to a further increase in the number of deaths from cancer, which accounted for 849 cases as compared with 686 in 1931. The epidemic of measles early in the year was the worst ever experienced in the city, notifications numbering 8,786. This figure, however, represented only the first cases occurring in each household, so that the total number affected must have been at least double. Over 50 per cent. occurred in children under 5 years, and there were eighty-two deaths. The report deals with an investigation into atmospheric pollution in the city. The clearest portion of the day was found to be at 3 a.m., and the smokiest between 9 a.m. and 10 a.m., with a secondary maximum at 7 p.m. These maxima appeared to coincide with the times of stoking domestic fires to cook meals; the greatest volume of smoke in Edinburgh was contributed by domestic fires.

Aberdeen University Graduation

At the summer graduation of Aberdeen University the honorary degree of LL.D. was conferred upon William James Mayo, M.D., of the Mayo Clinic, Rochester, Minnesota, U.S.A. The Dean of the Faculty of Law, in presenting Dr. Mayo, said that in him Aberdeen acclaimed a surgeon of international reputation, for the Mayo Clinic had been for many years a Mecca of those who wished to be freed from suffering. The methods and resources of this clinic had always been placed unreservedly before the medical profession, and the pre-eminence of Dr. Mayo's skill had been reflected in the many honours bestowed upon him. The ties between Aberdeen and the United States were numerous, and it was interesting to remember that in 1765 the University had trained certain physicians who subsequently helped to staff the medical school in Philadelphia. The present year was the jubilee of Dr. Mayo's entrance upon the medical profession, and the University of Aberdeen wished to pay its homage to one of the greatest surgeons of his time. Principal Sir George Adam Smith reviewed the progress of the University during the academic year 1932–3; the number of students had been 1,287, as compared with 1,252 last year. The students were to be congratulated on their success in raising over £4,000 for charities, especially hospitals of the city, during their gala week. Among the ordinary degrees conferred were those of M.B., Ch.B. on twenty-one graduands and of M.D. on seven.

England and Wales

Committee on Hospital Costs

Sir Hilton Young, the Minister of Health, has appointed a Departmental Committee whose terms of reference are:

"To consider and report on the questions of the capital cost of construction and the annual cost of maintenance of the following classes of public buildings provided by local authorities—namely, hospitals (including mental hospitals), public assistance institutions, mental deficiency institutions maternity homes (including maternity departments newly constructed or added to hospitals), and baths and wash-houses special regard being paid to (*a*) the establishment and periodic revision of standards, (*b*) modern methods of construction, and (*c*) the possibility of securing a reduction in present costs without impairing the efficiency of the buildings for the purposes for which they are designed."

The Committee is appointed in pursuance of a recommendation made by the Committee on Local Expenditure in their Report (Cmd. 4200) of October, 1932, and in accordance with the announcement made in the Minister's Circular 1311 of March 22nd, 1933. Its members are: Sir L. Amherst Selby-Bigge, Bt. (*Chairman*), Mr. J. Allcock, Mr. N. B. Batterbury, Dr. H. W. Bruce, Mr R. C. Cox, Dr. J. Ferguson, Mr. J. Kirkland, Dr. T. S McIntosh, Mr. R. H. P. Orde, Mr. L. G. Pearson, Mr. A. Scott, and Dr. W. Rees Thomas. The Secretary will be Mr. J. Topping of the Ministry of Health, to whom all communications relating to the work of the Committee should be addressed.

The "West London" Dinner

The West London Medico-Chirurgical Society held its fifty-first annual dinner on July 6th, at the Trocadero Restaurant, with Dr. Julius Burnford, the president, in the chair. After the loyal toast had been honoured the health of the society was proposed in a brief speech by the Very Rev. W. R. Inge, Dean of St. Paul's, who said that he expected a medical dinner would have consisted chiefly of vitamin dishes: cod-liver oil, lettuce and lemon, and vitamin D "to preserve us from rickets." Commenting on the medical profession Dean Inge said that he and his family were deeply indebted to it. The president, in reply, remarked that, as the West London Medico-Chirurgical Society dinner came at the end of a long series of medical dinners, during which he had listened to speeches from eminent members of various callings in life, he found it difficult to think of anything new to say. Societies like the Harveian and the Hunterian lent themselves to "titular" speeches. Mentioning by name the founders of the society, Dr. Burnford went on to show that the West London Medico-Chirurgical Society had progressed on a wide front. Dr W. S. C. Copeman, proposing "The Guests," began with a quotation from the Bible, and then took refuge in *Who's Who*. Welcoming the presence of Dean Inge, he expressed the hope that when he retired from St Paul's next year he would once more delight the world with his writings. Dr. Copeman then referred to each guest by name, with apt biographical allusion. Among those present were Lord Dawson, P.R.C.P., Sir Holburt Waring, P.R.C.S., Dr. Cecil Wall, Mr Warren Low, and Lord Justice Slesser. In a witty speech Lord Justice Slesser replied for the guests. He told the story of how he once had, against the better judgement of his clerk, interviewed in his chambers a mentally afflicted lady. This had taught him that the two professions of law and medicine should not be confused. Medicine, he said, was liberal and radical; the law was conservative. The response was ably seconded by Sir Holburt Waring, and Mr. B. A. Levinson proposed the president's health.

The Wrightington Hospital

The new Lancashire tuberculosis centre at Wrightington Hospital, near Wigan, has been formally opened by Sir George Newman. Reference to this institution and to its place in the Lancashire tuberculosis scheme appeared in the *British Medical Journal* of June 24th. In his address Sir George Newman quoted the precedents of the successful campaigns of the past waged against leprosy, plague, small-pox, and cholera. These diseases, though now banished almost completely from this country, were still flourishing in some other parts of the world, where, so far, it had not been possible to combine against them that force of will and determination which had proved so successful in England. Now the turn of tuberculosis had come, and a great part of the victory had been won already, for in the last sixty years its incidence and mortality had shrunk by three-quarters. Sir George traced the origin of the hospital to the two monastic infirmaries built in Athelney by King Alfred exactly a thousand years ago, and this retrospect led him to comment on the way in which the best of the medical traditions of the past were now being associated with the most modern discoveries in the task of eradicating tuberculosis. Traces still persisted in the new institution of ancient Greek and Arabian medicine. Laennec's spirit lived on in the stethoscope; the discovery by Koch of the tubercle bacillus, and by Röntgen of x rays, had afforded the means of diagnosis and treatment which were proving so effective to-day. Wrightington owed much to Lord Lister, and should never forget the name of Sir Robert Jones, the pioneer of orthopaedic surgery. This institution, unlike any other temple of healing in the country, was being built into a great national scheme for the prevention of tuberculosis. It afforded the best example in all England of the combination of means of prevention with methods of healing. Lancashire had the best scheme for attacking tuberculosis in any county; each year it was saving a thousand lives from tuberculosis. Children born now in that county had an expectation of life sixteen years longer than their grandfathers had had. England showed the lowest death rate of any civilized country in the world. Housing had improved, the nutrition of the population was better, and even the strain of unemployment had not brought about any increase in the sickness rate. All these were now bearing the fruit of a diminishing tuberculosis incidence. The new hospital was not only a temple of healing, but also of a most liberal education. Sir George Newman concluded his address with a warm tribute to the great part being played in the hospital and the home by the devotion and efficiency of modern nursing, particularly in the campaign against tuberculosis.

Inquests by London Coroners

The number of deaths reported to London coroners in 1932 was 8,360, an increase of 205 on 1931. Inquests were held in 3,491 cases, as against 3,603 in the previous year. Post-mortem examinations were made in 2,660 of the inquest cases, and in 2,588 of the other cases in which no public inquiry was necessary. A verdict of "Murder" was returned in twelve cases (two of them newborn infants), of "Manslaughter" in four, and two inquests were held in connexion with executions. The total number of suicides was 719, an increase of eighty-four on the previous year. The number of deaths from want of attention at birth increased from twenty-eight to forty. Death by accident was recorded in 1,892 cases, as against 2,050 in 1931; injuries accounted for forty-eight deaths, and there were fifty-two deaths by drowning. A verdict of "Death from natural causes" was returned in 573 cases, and there were four verdicts of "Cause of death unknown." Inquests on newly born children increased from fifty-one to sixty-seven; in twenty-seven cases it was decided that the children were stillborn. Excessive drinking accounted for fifty-four deaths, as against fifty in 1931. The cost of inquiries and inquests, exclusive of coroners' salaries and the rent of coroners' courts, was £22,395.

CORRESPONDENCE

Memorial to Dr. Carey Coombs

SIR,—Many of the friends and patients of the late Dr. Carey Coombs have expressed the desire of establishing in his memory some form of permanent memorial. With this object in view a committee of eight has been appointed, representing the Bristol University, the British Medical Association, the Bristol Medico-Chirurgical Society, and the Bristol General Hospital. We (the members of this committee) have decided to collect funds for the purpose of this memorial, and are satisfied that whatever sum is raised it will be possible to invest it in such a way as to keep Dr. Carey Coombs's name in perpetual remembrance. We may be able to endow a research studentship (an object very dear to Dr. Carey Coombs's heart) or a lectureship, associated with the Bristol University. The income of this sum will be given to Mrs. Carey Coombs for the next five years towards the education of her children.

Promises or cheques should be sent to Dr. Elwin Harris, jun., 13, Lansdown Place, Clifton. Cheques should be crossed "Coombs Memorial."—We are, etc.,

ERNEST W. HEY GROVES,
President, Bristol Medico-Chirurgical Society (*Chairman*).
CLARE SMITH,
Committee of the Bristol General Hospital.
EDWARD FAWCETT,
Dean of Medical Faculty, Bristol University.
C. E. K. HERAPATH,
British Medical Association and Bristol Royal Infirmary.
S. MARLE,
Bath Division of British Medical Association.
C. A. MOORE,
Bristol General Hospital.
J. A. NIXON,
Professor of Medicine, Bristol University.
H. ELWIN HARRIS, jun.,
Bristol Medico-Chirurgical Society (*Secretary*).

Clifton, July 9th.

Paying Patients at Voluntary Hospitals

SIR,—Dr. Rowland Fothergill, in his letter in your issue of July 8th, states that the Pay Beds Committee of King Edward's Hospital Fund proposed:

(*a*) That the accommodation provided in voluntary hospitals should be placed at the disposal of those of "moderate means" on the same terms and conditions as apply to the "sick poor," no payment for medical treatment being allowed.

(*b*) That the general practitioners should be "kept in contact with" these patients by communication, information, and advice.

(*c*) That the committee of management should lay down certain rules or limitations as to the medical practitioners who should be allowed to attend these patients.

The actual conclusions of the Pay Beds Committee on these subjects were:

(*a*) On the question of payment of medical fees, they stated that there was a difference of principle between wards where treatment was provided by the honorary medical staff free of charge and wards where the doctors received private fees; and that it was desirable that as many prospective pay bed

patients as possible should be enabled to place themselves in a position in which they can pay the full cost of maintenance in a pay ward and a medical fee as well.

(*b*) On the question of the relation with general practitioners, they quoted numerous different arrangements in force at different hospitals, and expressed the view that the maintenance of relations with general practitioners would be most important to the success of any large extension of the pay bed system if full use was to be made of the beds.

(*c*) On the question of rules or limitations as to the medical practitioners who should be allowed to attend the patients, they discussed the numerous differences in the existing rules, and the reasons given for them, and suggested that the question whether treatment should be confined to the medical staff or should be open to other consultants or to any registered practitioner was one that the governing body of each hospital should decide for itself.

—We are, etc.,

LUKE,
H. A. WERNHER,
Honorary Secretaries.

King Edward's Hospital Fund for London, July 11th.

Medical Practice and the Curriculum

SIR,—I am glad to see Dr. Camac Mellor, in your issue of July 8th, dotting the " i's " and crossing the " t's " of the argument for specialization in the medical curriculum. In a letter which appeared in your columns on June 11th, 1932, I pointed out that specialization for the practitioner was the inevitable outcome of the trend of events, and indicated that the universities would, by the force of circumstances, be compelled to rearrange the course of teaching for the student with this end in view.

I suggested further that while the authorities were considering the possibilities of change they might also bring about badly needed reforms in the method of teaching. The customary method of expounding subjects by lectures, for example, has nothing to recommend it so long as there are good textbooks available. It is a waste of time, increasingly resented by the more intelligent type of student. Discussion classes could be arranged to take the place of lectures. These would have the important advantages of explicating and elucidating obscure and difficult points, and at the same time of providing the student with an insight into scientific method and the estimation of evidence. The need for the propagation of the scientific attitude, in view of the prevalence of the variegated mystical and sham " systems," was never more evident than it is to-day.—I am, etc.,

London, W.1, July 10th. FREDERICK DILLON.

The G.P. and Midwifery

SIR,—The recent correspondence on this subject is of interest and importance to the profession. It is not astonishing that the general public who read the figures published regarding maternal mortality and morbidity should begin to wonder where the fault lies. Very naturally they blame the supposed inefficiency of the general practitioner, not the maternity hospital presided over by experts. The blame is often unfairly placed.

Speaking for the general practitioners of the older school as well as for the younger generation, my experience during forty-five years' practice in the Highlands of Scotland has been that in this large and scattered area midwifery is conducted with skill and followed by satisfactory results. We thank Dr. E. K. Mackenzie, whose pioneer ante-natal work is known and recognized by us, for his courageous defence of the maternity work of the general practitioner (*Journal*, June 3rd, p. 983). Dr. Mackenzie says that " the bulk of my patients live in cottages with no sanitary conveniences and only outside well-water supplies." This is true of most of the patients whom I have attended in Sutherland, except in the larger villages. But there is no puerperal fever; my last case dates back to the early nineties of last century. I have never seen a maternity case go wrong in the hills far away (ten to twenty miles) from the doctor. Difficult cases causing delay and much anxiety to the doctor occur as they do elsewhere—eclampsia, malpresentations, occipito-posterior positions, etc.—yet mothers and babies seem to do well. We have always acted on the belief that an anaesthetic is necessary for the examination and diagnosis of any case in which the diagnosis is not quite certain. Chloroform is practically the only anaesthetic possible in country work. It never fails, and, with care, unsatisfactory results are almost unknown. The letter of the Master of the Rotunda (*Journal*, July 1st, p 33) admirably sums up the whole question of chloroform in maternity work.

My conviction is that, generally speaking, the country doctor conducts his midwifery cases with less haste than his busier colleague in town practice can afford to do. There is less interference with the course of nature and correspondingly good results. Midwifery is his specialty. His knowledge is above the average, his judgement sound. He works mostly alone, and courage and self-reliance are developed. Most of our districts are served by " Queen's nurses." They are fully trained, and in addition hold the C.M.B. diploma. They give valuable help to the doctors in midwifery as well as in general cases.

Pace Dr. Mackenzie, my opinion is that in a widespread and thinly populated county such as this it would be of advantage to us in our work, and possibly therefore an additional safeguard to our patients, if we had at our disposal a few maternity beds attached to our county hospital to which, at the discretion of the doctor in attendance, a complicated midwifery case might be transported by ambulance. Dr. Mackenzie says at the close of his letter: " Thank God I shall be dead before that day comes . . ." [maternity hospitals in the Highlands]. Would he consent not to leave us if we ask for only a few maternity beds? I trust he would, for we should be very unwilling to hasten an event which his colleagues fondly hope is far distant.—I am, etc.,

Golspie, Sutherland, July 1st. JAMES B. SIMPSON.

SIR,—Every general practitioner must have appreciated the recent correspondence on midwifery in the *British Medical Journal*. Dr. Mackenzie's letter was excellent; and I should like to congratulate Dr. Kathleen Vaughan on her championship of the squatting position. The psychological side of maternity is well put by Dr. G. D. Read in his book *Natural Childbirth*. I feel that many of the articles in the public press on maternal mortality only result in scaring future mothers, and so do no good. My own experience of midwifery runs to about 1,500 cases (my actual records were lost when removing to another house), and I have had four deaths (one at least of which was unavoidable, being due to intraperitoneal rupture of a small ovarian dermoid during labour). This is not an alarming mortality; and I feel sure there is a no more alarming morbidity. My cases have included all presentations except mento-posterior (the only time I have heard the vagitus uterinus was in a face presentation), and I think I have had to use every obstetric instrument except a cephalotribe. My practice is not within easy reach of any hospital.—I am, etc.,

Barton-on-Humber, July 7th F. P. H. BIRTWHISTLE

Use of Quinine in Normal Labour

SIR,—Dr. G. C. Dorling's letter in your issue of July 8th (p. 79) does not do justice to my original paper in the *Journal* of January 25th, 1930. Neither Dr. Rees's letter of April 1st (p. 587), to which he refers, nor my paper had anything to do with the question of induction of labour by quinine. Both of us referred to the method of pre-natal quininization as a routine for cases of labour expected to fall within normal limits. Without going into details, the method consists in giving a small dose of quinine (1½ grains three times a day) for a period of three weeks before the anticipated date of labour, the object being to tone up the uterus and to try to ensure good contractions and good retraction. In the first 400 cases observed by Dr. Philip Jones and myself it was specifically noted—among many other considerations—that no tendency to retained placenta occurred. In a very much larger number of cases observed since then by my colleagues and myself this claim has been substantiated, and should any individual worker see one such case it should *not, without careful analysis, be blamed to the quinine.*

About twelve years ago, when pituitary extract had a great vogue for use in the second stage of labour, I saw three consecutive cases of retained placenta, and in my own mind I blamed the pituitrin. A year later one of these same cases again had a retained placenta with no pituitrin (and no quinine). This is but one more example of the extreme difficulty in medicine of distinguishing between " impressions " and " facts."—I am, etc.,

DOUGLAS A. MITCHELL,
Bath, July 8th. M.D.Lond., F.R.C.S.Ed.

Aetiology of Acute Rheumatism

SIR,—It is a well-authenticated fact that in temperatures above about 70° F. plague cultures can be splashed and the air around inhaled with impunity, but when the same thing is done at a very low temperature the workers get pneumonic plague. There is an almost exact correspondence to this in the behaviour of natural pneumonic plague. In the Tropics pneumonic plague may kill every person in a house, and yet it never becomes epidemic, and an unmasked doctor can generally visit the cases with reasonable safety; but in a Manchurian winter pneumonic plague spreads as an epidemic, and almost all unmasked persons who handle the case get the disease and all properly masked ones escape. There are two theories to explain the above: one that warm air attenuates the bacillus in the droplet, and the other that cold air weakens the defence of the mucous membrane. When an Eskimo enters his dwelling he throws off all his clothes and lives completely naked in a temperature of about 70° F.; at other times he is mostly hunting. Thus, so far as droplet infection is concerned, he is virtually in the Tropics.

If acute rheumatism is propagated by droplet infection then the anomaly of the Eskimo, pointed out by Dr. E. C. Warner in the account in the *Journal* of June 17th (p. 1060) of " Soil and Climate in Relation to Rheumatic Diseases," disappears. It may be considered almost an axiom that if an acute febrile disease tends to be relatively rare or mild within 15 degrees of the Equator near sea-level and common in cool and temperate climates (diphtheria, scarlet fever, measles, pneumonia, whooping-cough, rubella, influenza, common " colds," etc.), or if it occurs as winter epidemics at the tropical margin which are rapidly checked by the advent of summer (small-pox, cerebro-spinal fever, etc.), then it is due to an organism which enters the body via the air. Acute rheumatism and scarlet fever stand, I believe, almost by themselves in their intense objection to tropical conditions; if the infection of the one is received via the air that of the other probably is also.

As a medical man I spent twenty-three years in Hong-Kong—about the third largest port in the world as regards tonnage of shipping and a city of more than half a million people, with heavy passenger traffic to and from North and South America, the Philippines, China, Indo-China, and Malaya—and I never saw or heard of a case of acute rheumatism arising there; nor did I ever see a lesion caused by it, though I examined about 4,000 hearts of Chinese children post mortem. Scarlet fever sometimes rages in epidemic form in Shanghai, whence there is a large passenger traffic to Hong-Kong, about four days' steaming to the south: cases arrive in Hong-Kong and have been known to infect children using the same room, but no epidemic is ever set up.

In a Hong-Kong summer dewdrops hang upon the trees all day, pillows smell of mould twenty-four hours after drying, pictures go mouldy on inside walls, match heads drop off, the clouds blow through your rooms, and the rain bird toils all day; but there is no acute rheumatism. *Rattus norvegicus* has been common in Hong-Kong for at least twenty-five years, and there are many sewers. In 1906–9 *Xenopsylla cheopis* was common and *Ceratophyllus fasciatus* very rare. The plains of India are not tropical in winter; people huddle together there for warmth in a temperature under 55° F. I have seen them in Punjab villages far from the Hills so closely packed together, in a temperature not much above freezing point, that I could not walk between them.

I have never heard of a therapeutic measure in which cases of acute rheumatism or scarlet fever were kept in a humid temperature of about 80° F. night and day, but I consider it most important to try such a measure. In acute rheumatism we might hope that it would prevent relapses and shorten the duration of the disease. In scarlet fever we might hope that the treatment would pay for itself by diminishing return cases and shortening the stay in hospital. There must, I think, be plenty of tomato houses in the hands of the banks which could be adapted to the purpose. Better grapes, better melons, better tomatoes, and better cucumbers are grown in English coal-heated fruit houses than in their native lands, because the temperature and moisture can be regulated to a nicety. Perhaps we could go one better than the Tropics in the treatment of some diseases.—I am, etc.,

Hassocks, Sussex, June 24th. C. M. HEANLEY.

Prophylaxis of Malaria

SIR,—May I be permitted to endorse the letter of Dr. O. G. Wilde in your issue of July 1st (p. 35) on the subject of malaria and quinine prophylaxis. I do so with the greater confidence since my experience covers both West Africa and Malaya, of whose medical service Dr. Hoops was until lately a most distinguished member.

I served in West Africa in a most malarious up-country district for twenty months during 1925–6. Of anti-malarial work as it is known and carried out in Malaya there was none. I accepted, in common with most others, the practice of the daily dose of quinine, and during the whole of my service took it religiously. In the small community in which I lived two of the other Europeans developed malaria. In both cases they had, against all advice, omitted to take quinine. The presence of malaria in this area was not in doubt, a very high proportion of the African children having enlarged spleens, and typical malarial attacks being common. Following my return from Nigeria I spent three years in the Malayan Medical Service. There I found that the idea of quinine pro-

phylaxis was scorned, but that attacks of malaria among Europeans in malarious areas were assumed to be almost unavoidable, and accounted for much invalidism. I could not but contrast this with the attitude to malaria in West Africa, where the individual who went down with fever was looked upon as, in most cases, one who was simply paying the penalty of neglect of an obvious precaution.

My work in Malaya took me frequently to malarious areas, chiefly on rubber estates, where it was no uncommon thing for the European staff to suffer from malaria. While on these visits I regularly took quinine. Neither then nor since have I ever suffered from malaria. On my departure from Malaya I wrote a letter on this subject, which was duly published in the *Malayan Medical Journal*. I would agree with Dr. Hoops that quinine prophylaxis as a method of *mass* attack on malaria does not in practice work, but from my experience, and from the experiences of others, I believe that to be largely due to the fact that the quinine is either not taken or else that it is got rid of at the earliest opportunity. But where quinine prophylaxis has been honestly put to the test by individuals themselves, the result, so far as I have been able to discover, has always been highly satisfactory. The personal prophylaxis of malaria by the taking of quinine badly wants a real trial in Malaya.—I am, etc.,

March, Cambs, July 1st. THOS. C. LONIE.

SIR,—Dr. O. G. Wilde's letter in your issue of July 1st (p. 35) interests me, and from my own somewhat prolonged experience in dealing with malaria in Assam I can in very large measure confirm what he writes regarding the high value of quinine prophylaxis in that disease. Without doubt it is the irregular or non-quinine taker who suffers from continual malarial attacks. The person who takes the regular daily dose of 5 grains of quinine is, as Dr. Wilde states, not immune, but gets far less frequent attacks, and attacks as a rule milder in character. My work in Assam lay for over fourteen years in highly malarious districts, where subtertian malaria was endemic and cases of blackwater fever of lamentably frequent occurrence. With Dr. Wilde, I never saw a case of blackwater fever in a person who took quinine regularly, and I proclaimed this constantly as a definite insurance against this deadly disease. Blackwater fever, I found, occurred pre-eminently in people who despised prophylactic quinine, and who suffered from repeated, more or less neglected, attacks of subtertian malaria, or, again, in persons who took heavy doses of quinine only on the occurrence of a malarial attack, dropping the treatment before the infection was completely overcome. In this type of person any prolonged fatigue, unusual exertion, or chill precipitated an attack of blackwater fever, often, in the case of members of the European community, with fatal results.

Now all this is indubitably true, although appearing much at variance with Dr. Hoops's statement (June 10th, p. 993) of the uselessness of quinine prophylaxis in malaria; but I think the secret of the divergence of opinion lies in the *intensity of infection*. I am satisfied that the results of administering quinine in prophylactic doses to a coolie population can scarcely justify the expense, and to depend on this method for the control of malaria on a tea or rubber estate is futile. Prophylactic quinine here cannot take the place of measures directed against the mosquito, although it is perhaps of some limited use as a supplementary means. Where it is of high proven value is in the case of Europeans and others who live in reasonably sanitary surroundings, who are accustomed to the use of mosquito nets, or who inhabit screened houses. In dealing with a coolie population success must be looked for primarily in anti-mosquito work, and then in the thorough treatment of malaria cases as they arise with quinine or, as Dr. Hoops suggests, with atebrin, which seems such a remarkable therapeutical advance—especially in children, the reservoirs of infection.—I am, etc.,

Newport, July 3rd. CHARLES E. P. FORSYTH.

SIR,—I am in agreement with Dr. O. G. Wilde's letter in the *Journal* of July 1st (p. 35). After nearly twenty years in Nigeria I can say that the majority of the off-duty cases diagnosed malaria were among those who did not take quinine regularly. I was in a moderately healthy district, but the malaria was always among those who were not careful to take their daily 5 grains. I am of opinion that only one salt of the drug should be taken—namely, the bihydrochloride—as I have seen the tablets of sulphate in the faeces almost as they have been taken. All my cases of blackwater occurred among persons who either did not take quinine or only took it when they felt ill. A great deal of harm is done by such sweeping statements as those referred to by Dr. Wilde. I have never suffered from malaria, but have always been careful to take quinine daily, and an extra dose if I had been exposed to rain or had done extra hard journeys. I always continued quinine daily for two months after arrival in England, and have never felt any ill effect. The wise people in West Africa are those who take their 5 grains of quinine daily.—I am, etc.,

J. R. C. STEPHENS.
St. Austell, Cornwall, July 3rd. W.A.M.S. (ret.).

Vaccines in Coryza

SIR,—I have read with interest Dr. F. Porter's remarks (June 24th, p. 1127) on my paper "Autogenous Vaccines in Acute Coryza" in the *Journal* of June 10th (p. 996). In view of the fact that three distinct groups of observers—namely, von Sholly and Park, Jordan and Sharp, and Ferguson, Davey, and Topley—all carried out investigations into the value of stock anti-catarrhal vaccines on a scale which can only be described as colossal, and came to the unanimous conclusion that the protective effect of these vaccines was *nil*, I feel justified in treating with some scepticism Dr. Porter's 70 per cent. successful protection, especially as he "cannot give any accurate statistics." Dr. Porter states that "the proof of the efficacy of vaccine treatment lies in the fact that a large number of patients demand it annually." It is also true that the demand for patent medicines is enormous, but I doubt if Dr. Porter would regard that as a proof of their therapeutic efficacy.

With regard to the stage of the disease at which treatment was given, patients were, of course, treated as far as possible in the absence of acute symptoms. The question of vaccine dosage is a difficult one, but it seems to me that vaccines may be used for two purposes in therapeutics: first, to immunize the patient against the organism in question, in which case such evidence as is available would suggest that the larger the dose and the greater the reaction obtained the more effective is the subsequent immunity; and, secondly, to desensitize a patient who is supersensitive to a bacterial toxin, in which case minute doses are necessary and reaction is to be avoided. Dr. Porter would appear to use his vaccines in the second way, and it is, of course, not impossible that sufferers from coryza may be supersensitive to the toxic products of the causal organism, though I have never heard of any evidence to that effect.

With regard to the omission of the *Micrococcus catarrhalis*, in a somewhat extensive investigation of the

bacteriology of the respiratory tract I found Gram-negative cocci of the *catarrhalis* type to be present in 100 per cent. of normal throats and about 40 per cent. of normal noses. In the very extensive work done on the aetiology of acute coryza in the last fifteen years, as far as I am aware only one observer has suggested that the *Micrococcus catarrhalis* played a primary part; and as his observations were confined to the study of a single case, I think they may be discounted. The only justification for the extensive use of vaccines for the prophylaxis of the common cold is that a certain number of individuals appear to benefit from them, and that these can only be selected at present by the process of trial and error.—I am, etc.,

Leeds, July 4th. L. HOYLE.

Perforating Ulcer of Foot

SIR,—Messrs. James and Matheson's article in the *Journal* of July 1st (p. 12) interested me greatly. Personally I have found that a periarterial sympathectomy upon the femoral artery, performed thoroughly—that is, dissecting completely the adventitia for at least three and a half inches—is an effective method in cases of perforating ulcer of the foot. My most convincing case was operated upon at Oldchurch Hospital, Romford, last December. The patient was a man of 61, and the ulcer had been present for the last thirty years. During this time it had never healed up, even for a short time, in spite of all kinds of treatment, which had included periods of rest in bed for upwards of three months. After the periarterial sympathectomy the ulcer healed completely within five weeks. I saw him a fortnight ago. The sole of the foot was quite healthy, and he had been wearing boots and walking normally during the interval.—I am, etc.,

London, W.1, July 4th. HAMILTON BAILEY.

Otorrhoea

SIR,—Mr. E. Watson-Williams, in his interesting address (*Journal*, July 8th, p. 47) refers to the treatment of chronic otorrhoea by zinc ionization, and among other things says that the result would be the same whether the electric current were used or not.

In zinc ionization two factors have to be considered—the zinc and the current. After the ear has been cleansed and filled with zinc sulphate solution (one-quarter of one per cent. in strength), the positive electrode is placed in the ear and the positive zinc ions only are introduced into the film of infected discharge adhering to the surface and into the superficial cells of the tissues. The quantity of ions introduced, and the depth to which penetration extends, depends solely on the strength and duration of the current. Tympanic cavities are approximately of the same size. The dose was determined empirically. It is found that with a current of 3 milliamperes for ten minutes the dose of zinc is satisfactory. Zinc ions readily combine with albumin to form a firm, insoluble precipitate. This precipitate is a bad culture medium for bacteria. As the firm precipitate or coagulum of zinc and albumin is insoluble, the action of the zinc is confined to the tissues into which it has been introduced. Subjacent tissues are not irritated.

The factors essential to success in local antisepsis are that the action of the drug should be inimical to the activities of bacteria, and that tissues subjacent to the surface treated should not be irritated. Zinc ionization fulfils these desiderata, and it is the only antiseptic treatment for suppuration known to me which is worthy of the name. The majority of cases of chronic suppuration in the ear, due to sepsis alone in an accessible position, cease to discharge after one treatment. Can this be said of any other method of antiseptic treatment? It is owing to its efficacy that it is of economic importance.

Nearly ten years ago an aural clinic with one session of two and a half hours a week was added to the school medical service at Tottenham. The school population was 25,000. There were a large number of cases of chronic otorrhoea. These cases were examined, and the cause of chronicity determined in each. For those cases of considerable severity, in which sepsis alone in an accessible position was considered to be the responsible factor, zinc ionization was the standard form of treatment. None of the cases received any treatment in the intervals between their visits to the clinic. In those in which there were factors additional to sepsis, such as polypi or granulations, these were first treated. The majority of those cases in which the area of sepsis was inaccessible required a mastoid operation, and were sent to hospital. There has not been a waiting list for several years. Every acute case can now be seen within a few days of its discovery. Chronic otorrhoea is almost absent from the elementary schools at Tottenham. The method which has been the basis of treatment for chronic otorrhoea is zinc ionization.—I am, etc.,

London, W.1, July 8th. A. R. FRIEL.

Glycosuria in Cerebro-spinal Fever

SIR,—We think the following case might be of interest:

On June 17th a boy of 13 travelled to the seaside, bathed, and returned home the same evening, apparently well. During the next day (18th) he vomited three or four times, complained of abdominal pain, but was better at 10 p.m. Half an hour later he became incoherent and drowsy, throwing himself about the bed.

At 4 a.m. on the 19th one of us was called in, and found a well-nourished boy in a condition of stupor, lying on his side with knees drawn up. His pupils were widely dilated, and ophthalmoscopic examination revealed no abnormality of retina or disk. The patient showed mental irritation when touched: he was incontinent of urine and the rectal temperature was 103°. Rigidity of the muscles of the neck was not present, but the boy strongly resented our attempts to move his legs. Urine was obtained through a catheter, and it was found that 8 drops were sufficient to reduce 5 c.cm. of Benedict's solution to an orange colour as soon as boiling point was reached, while the ferric chloride and Rothera tests for aceto-acetic acid were strongly positive.

We were unable to satisfy ourselves that the boy had suffered from thirst prior to the present illness, but the fact that the urine apparently contained more than 2 per cent. of sugar and also aceto-acetic acid made it seem improbable that the patient's condition was caused by meningitis; therefore the diagnosis made was diabetic coma, onset occasioned by febrile catarrh, and our treatment during the day is recorded.

June 19th	Urine		Insulin Given		Temperature
	Sugar	Aceto-acetic acid			
6.30 a.m.	++	++	40 units (intravenous)	Glucose given in amount to correspond to insulin	98.6°
9 a.m.	++	++	40 units (intravenous)		101.0°
12 p.m.	trace	—	20 units (hypodermic)		100.4°
2 p.m.	trace	—	10 units "		—
6 p.m.	trace	—	5 units "		101.0°
9.30 p.m.	—	—	5 m adrenaline given		101.6°

At the end of this time the stupor had lightened, but there was no marked improvement. We thought that there were signs of hypoglycaemia at 8 p.m., but a large amount of glucose could then be taken by mouth. Next morning (June 20th) the patient developed twitching of the face muscles, and later general convulsions. The cerebro-spinal

fluid was found to be under pressure: it was cloudy, and contained pus cells and Gram-negative cocci. Serum was administered by the intrathecal and intravenous routes, but the boy died during the night of the 21st.

It is well known that glycosuria does occur in association with meningitis, but that such a high percentage of sugar should be found seems unusual. At any rate the occurrence was sufficient to cloud our judgement for a while, and encouraged us foolishly to disparage the significance of the clinical manifestations.—We are, etc.,

G. S. W. EVANS.
O. F. SYDENHAM.

Crewe, June 24th.

"Recurrent Volvulus of the Pelvic Colon"

SIR,—The article by Messrs. Ligat and Overend under the above title (*Journal*, July 1st, p. 7) will serve a useful purpose if it brings out the fact that elongation of the pelvic colon is, under certain conditions, a potent source of trouble. The authors stress the liability of such an elongated loop to torsion either on its transverse or longitudinal axis. This, however, is not the only way in which an elongated pelvic colon can give rise to trouble. When such a loop is loaded with faeces it prolapses into the pelvis, and by making the opening up of the pelvi-rectal angle difficult, and so preventing the passage of material into the rectum, it prevents the proper establishment of the defaecation reflex and induces a particular type of constipation.

In a paper in the *Lancet* (August 7th, 1926) I pointed out this fact, and gave details of four cases in which the symptoms were severe enough to call for excision of the loop, but without the actual occurrence of volvulus. I also pointed out that in children such a loop, full of material and prolapsed in the pelvis, might give rise to anaphylactic phenomena such as asthma, urticaria, etc. Since the publication of that paper I have had cause to resect the elongated pelvic colon loop in a further eighteen cases. With end-to-end anastomosis and the passage of a tube up the anus and through the junction there has been no mortality, and the relief to the patients has been striking. Mr. Ligat, in his classification of types of elongated pelvic colon, rightly separates the megasigmoid, in which there is gross dilatation of the lumen, from the other types, and attributes it to a neuro-muscular imbalance. Such a distinction is important, as while operations on the abdominal sympathetic may, and in some cases do, improve this type of case, they can be of no value in the more usual type of elongation without dilatation, to which they are sometimes erroneously and unfortunately applied.—I am, etc.,

E. G. SLESINGER.

London, W.1, July 2nd.

Cancer Families

SIR,—The family history of cancer reported by Mr. Harold Dodd in the *Journal* of July 1st (p. 36) is remarkable, and offers further evidence, if needed, of the influence of the inherited factor in the aetiology of this disease. I have myself been acquainted with a family in which the mother died of cancer of the breast, the eldest daughter died of visceral malignant disease (cancer or sarcoma), and the second daughter also died from cancer of the breast, after operation. Such cases as these, many of which are known, indicate the importance of investigating the existence of precancerous changes in the blood and tissues, which must exist if the disease is inherited, and must long precede any outward manifestation. In this way only can any real cure for cancer be discovered. There are, however, signs of a revival of research on these lines.—I am, etc.,

C. F. MARSHALL, F.R.C.S.

Westcliff-on-Sea, July 3rd.

Obituary

THE LATE SIR WALTER FLETCHER

Dr. JOHN H. HANNAN (pathologist, Hospital for Women, Soho) writes: May I, as a research worker of some ten years' standing, pay a last tribute to the memory of one who was no "defeatist" in medical research. Sir Walter Fletcher always insisted upon the importance of strict "control" work, and it was typical of him to ask me to investigate the possibility of spontaneous cure of carcinoma before publishing my investigations concerning the various therapeutic agents used in the treatment of this disease. In these days, when the public appear to be losing confidence in qualified medical practice, we are in urgent need of men like Sir Walter. So frequently we research workers find nothing but destructive criticism as a reward for our efforts, whereas in meeting Sir Walter one could always count upon a man who listened, criticized, offered constructive suggestions, and hoped that our work would reach a successful conclusion. Men like Sir Walter Fletcher are but rarely born, and I pay my final tribute in ancient language. Let us be among those who, like Sir Walter, "at once mark the goal"—*simul ultima signant*.

THE LATE DR. FORD ANDERSON

Dr. ROBERT CARSWELL writes: The obituary notice of Dr. J. Ford Anderson would be incomplete without a reference to what was undoubtedly one of the dominant motives of the last twenty-odd years of his life. As a member of the central committee of the British Medical Association which formulated the views of the Association and of the profession generally before the passing of the National Insurance Act of 1912 he has recorded how, when the passing of the Act was imminent, the profession rose like one man to protest against it—97 per cent. being the figure. And from that time to almost the day of his death he never ceased to evince the most active and uncompromising hostility against those revolutionary measures which so fundamentally altered the practice of medicine in his time. Like his friend the late Dr. Alexander Blackhall-Morison, he considered that the National Health Insurance Act brought in its train to the medical profession loss of independence, loss of scientific spirit, and also introduced a commercial outlook which had hitherto been foreign to the profession, and he liked to compare his fellow members of the National Medical Union, of which he was one of the founders, to those clergy (of whom his father was one) who seceded from the Church and faced hardship for conscience' sake in the Disruption of the Church of Scotland in 1843. Among a number of contributions to the journal of the above society a paper of his entitled "Reminiscences of Lister" is well worth perusal. It has been reprinted by the society in pamphlet form. Also an article on the Oath of Hippocrates (January, 1930), prefaced by a translation of the Oath and a reproduction of a third century head of Hippocrates, is of much interest. The extraordinary span, not only of time but of thought, covered by his life is brought home to the reader of the last-named article by his recollection of an old gentleman-cupper in a swallowtail coat who called at the ward door of the Middlesex Hospital daily in 1863 after the physician's visit, and said, "Any orders for me, Sister?" This, he says, was probably the last of the barber surgeons These notes are written as an affectionate tribute

Dr. WILLIAM BARRON, who died last month at his residence in Letham, Forfarshire, had been engaged for fifty years in general practice in that district He received his medical education at Aberdeen, where he graduated M.B., C.M. in 1878, and proceeded M.D in 1885. He was medical officer and public vaccinator for Dunnichen and Carmylle, and part-time medical officer for Forfar. Notwithstanding the claims of a widespread practice Dr. Barron found time to identify himself actively with the social life of the community He took special interest in freemasonry, education, horticulture, and the

promoting of local athletic sports. He was a member of the British Medical Association. One of his colleagues, Dr. John Cable of Forfar, writes of him: "A man of simple tastes, wide sympathies, and modest bearing, he won and kept a large circle of friends. His intellectual acumen and wide mental vision often showed a touch of real genius. Behind a shyness and reserve of manner he could think great thoughts, and give them telling expression. A man of wonderful ability, strong tenacity of purpose, and intense human sympathy, he leaves behind him the fragrant memory of a noble life, which will always be cherished by everyone who knew him."

Universities and Colleges

UNIVERSITY OF LONDON

At a meeting of the Senate on June 21st it was resolved to institute a University Readership in Pharmaceutics, tenable at the College of the Pharmaceutical Society.

Professor A. E. Boycott, M.D., F.R.S., was reappointed Director of Research under the Charles Graham Medical Research Scheme for one year from September 1st.

The Regulations for the B.Sc. (General) Degree for Internal Students were amended by the insertion of the following after the first sentence on page 275 of the Red Book, 1932-3:

A student who, subsequently to passing the Intermediate Examination in Science as an Internal or External Student or being exempted therefrom under the Regulations for Advanced Students, had completed the course of study for the Second Examination for Medical Degrees, Parts I and II, as an Internal Student, may enter for the B.Sc. (General) Examination in Chemistry, Physiology, and Human Anatomy and Morphology, provided he has attended a further course of study for the B.Sc. (General) Examination extending over not less than one term and has complied with the Regulations in all other respects.

Professor J. M. Woodburn Morison, M.D., has been appointed representative at the Fourth International Congress of Radiology, to be held at Zürich from July 24th to 31st.

Sir Cuthbert Wallace, F.R.C.S., has been elected chairman of the Graham Legacy Committee.

The degree of Ph.D. in helminthology has been conferred upon R. K. Khanna; and M.Sc. in biochemistry upon N. F. Maclagan, M.B., B.S.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—E. T. Baker-Bates, A. B. Follows, W. W. Gerrard, B. T. J. Glover, J. H. Hughes, T. L. Hughes, E. L. Rubin.

M.B., CH.B.—*Part I* (1929 Regulations): *W. M. Beattie, *A. C. Brewer, *A. Cohen, G. V. Craine, Phillis Dingle, V. K. Drennan, B. J. Green, R. L. Hartley, Mary M. Hurst, G. E. Jones, Joan G. Jones, J. R. Jones, E. W. Knowles, H. S. Lanceley, Ethna W. Little, Sheelah Little, F. R. Neubert, W. Parke, *J. Pinkerton, J. G. Rogers, W. I. D. Scott, A. R. Sibbald, E. G. Watson. *Passed in Individual Subject:* C. F. Crampton, H. W. F. Croft, H. R. G. Davies, Clarice Hughes, A. G H. Menzies, G. S. Robinson (Pharmacology and General Therapeutics). *Part A* (1924 Regulations): J. Morgan, T. H. Pierce. *Passed in Individual Subject:* H. H. L. Pentz (Pharmacology and General Therapeutics). *Part II* (1929 Regulations): A. B. Concanon, ‡Bessie Dodd, Jannett C. Evans, F. A. Frank, F. Harrison, ‡E. W. Jones, J. R. Jones, A. O. Karstaedt, Kathleen M. Kavanagh, †A. J. McCall, †Annie A. Merrick, L. Millward, Margaret F. Proctor, W. I. D. Scott, S. Shulman, ‡A. Speight, †S. L. Strange, R. P. Tong, J. K. B. Waddington, M. M. Wallis, Margaret C. Winter. *Passed in Individual Subject:* G. S. Robinson (Forensic Medicine and Toxicology).

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part B:* J. R. Burrows, T. P. Twomey.

D P H—*Part II:* §P. L. C. Carrier, P. P. Fox, D. O. Hughes.

* Distinction in Pharmacology and General Therapeutics.
† Distinction in Forensic Medicine and Toxicology.
‡ Distinction in Public Health.
§ With Distinction.

The following awards have been made in the Faculty of Medicine: *John W. Garrett International Fellowship in Bacteriology*, Dr. E. R. Jones. *Robert Gee Fellowship in Human Anatomy*, Dr. A. S. Kerr. *Holt Fellowship in Physiology*, Dr. G. R. Griffith. *Holt Fellowship in Pathology*, Dr. G. A. C. Lynch. *Johnston Colonial Fellowship in Biochemistry*, Mr. J. Devine. *Lady Jones Research Fellowship in Orthopaedic Surgery*, Dr. W. S. Creer. *John Rankin Fellowship in Anatomy*, Dr. W. Bullock. *Thelwall Thomas Fellowship in Surgical Pathology*, Dr. H. G. Hanley. *University Graduate Scholarship in Medicine and George Adami Prize in Pathology*, Mary M. Hurst. *Junior Lyon Jones Scholarship*, G. L. Manson; *proxime accessit*, C. J. Williams. *Samuels Memorial Scholarships:* (Medicine) Dr. J. Libman, (Surgery) Mr. M. Silverstone, (Obstetrics and Gynaecology) Mr. T. N. A. Jeffcoate. *William Mitchell Banks Bronze Medal*, R. R. Hughes. *Silver Medal in Forensic Medicine and Toxicology*, A. J. McCall; *proxime accessit*, Annie A. Merrick. *Kanthack Medal (Pathology) and Silver Medal in Pharmacology*, A. C. Brewer. *Owen T. Williams Prize*, J. D. Hay.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examinations indicated:

M.D.—Constance N. Jenkinson.

FINAL M.B., CH.B.—*Part II:* F. R. P. O'Hara-Proud (with second-class honours), L. Botros, R. M. Edelman, Ursula S. Nutt, S. J. Rabinowitz, F. Rodgers, D. C. Waddy.

VICTORIA UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—*†T. F. Heslop, W. Bradley, T. W. Brindle, Edna Circuitt, R. K. Clough, E. Davis, P. R. Evans, W. G. H. Hughes, J. F. E. Johnson, R. Judson, A. R. Kennedy, N. Launer, J. C. Morris, R. Nightingale, H. C. Palin, D. C. Racker, Florence C. Read, L. Rich, W. Sagar, J. Schofield, N. Shlosberg, J. N. Strauss, †E. Vernon, C. S. Walker, J. L. D. Williams. *(Part I) Forensic Medicine and Hygiene and Preventive Medicine:* H. Baker, A. S. Bullough, W. P. Cargill, N. Copeland, P. D. H. Cran, J. Curry, Annie M. Dawson, I. H. Flack, N. Goldstone, C. Hancock, A. Harris, H. Harris, H. Hempling, B. P. Hill, J. A. Hobson, F. Janus, R. H. Jobson, S. H. O. Jones, N. F. Kirkman, D. H. Mackay, A. E. Martin, Barbara de V. Mather, E. L. Patterson, Winifred Porter, W. K. Spencer, C. Tetlow, A. McN. Tomlinson, J. A. A. L. Woodhead. *Pathology and Bacteriology:* J. Boardman, Monica D. Boyle, G. D. Harthan, R. E. Hirson, T. S. B. Kelly, H. D. B. North, J. Starkie. *Pharmacology:* J. Cohen, F. P. Ellis, S. Franks, W. E. Kershaw, A. L. Robertshaw.

* With second-class honours. † Distinction in Obstetrics.
‡ Distinction in Medicine.

On July 8th women graduates of the Victoria University of Manchester gave a reception to celebrate the fiftieth anniversary of the admission to Owens College of women on the same terms as men. In commemoration of this jubilee the University conferred the honorary degree of D.Sc. on Dr. Harriette Chick, C.B.E., of the Lister Institute of Preventive Medicine.

UNIVERSITY OF BRISTOL

The Council of the University has appointed Miss Doris May Stone, M.D., D.Ph., junior pathologist in the Department of Preventive Medicine.

UNIVERSITY OF ABERDEEN

At the graduation ceremony on July 5th the honorary degree of LL.D. was conferred upon William J. Mayo, M.D., D.Sc., LL.D., F.R.C.S., Chief of Staff of the Mayo Clinic, Rochester, Minnesota, U.S.A.

The following degrees were conferred.

M.D.—*J. B. Ewen, *D. C. Robb, *R. D. Stuart, *R. Sutherland, J. A. Dawson, R. H. G. H. Denham, R. G. Henderson.

M.B., CH.B.—I. A. Anderson (first-class honours and passed Final Medical Professional Examination with distinction), A. M. Rennie, J. R. S. Third.

* Awarded commendation for thesis.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE

On October 28th, 1932, the Court of Governors of the University of Durham College of Medicine, Newcastle-upon-Tyne, informed Lord Londonderry, Chancellor of the University, that they considered it advisable that he should institute an independent inquiry into the administration and constitution of the College. The Chancellor also communicated with the Council of the College asking their assistance and co-operation in the matter, and at his invitation Sir Amherst Selby-Bigge held an inquiry at Newcastle early this year. Sir Amherst [illegible] ow reported his findings to the Chancellor. [illegible] a statement by Lord Londonderry to the Newcastle *Evening Chronicle* that it is a private report and will not be published, summaries and extracts have appeared in that and other newspapers during the past few days. The report, according to the *Daily*

Telegraph of July 10th, "declares that complaints of maladministration brought against College Council were not substantiated. The hope is expressed that, the inquiry having afforded an opportunity for expression of views and ventilation of discontents, those interested in or concerned with the College will now put aside all disputes and concentrate on promoting its welfare. A definite charge of maladministration was brought against the Council, the report states, in respect of its treatment of Professor H. J. Hutchens (Heath professor of pathology and bacteriology) It was urged that the Council's action was not bona fide, reasonable, fair, and in accordance with university usage Regarding that complaint, in my own opinion, states Sir Amherst Selby-Bigge, the allegation of mala fides is not established It must be remembered that the Council's act was not to remove him as professor, but to terminate his engagement as lecturer in the College, leaving him in possession of the post of Heath professor of the University. It is not for me to say whether or not the professor was well advised in rejecting the terms of retirement offered him."

UNIVERSITY OF DUBLIN

At the degree ceremony in Trinity College on July 5th, presided over by the Vice-Chancellor, Sir Thomas Moloney, the honorary degree of Sc.D. was conferred on John Scott Haldane, M D , F.R S , Fellow of New College, Oxford, and Honorary Professor and Director of Mining Research in Birmingham University.

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M D —S. A. Clark, N. M'I. Falkiner, Marie A. Hadden, Hope Trant.

M CH —P A Hall.

FINAL MEDICAL EXAMINATION —*Part I, Materia Medica and Therapeutics, Pathology and Bacteriology:* *W A Gillespie, D S. Quill, H Pringle, H J. Anderson, G. W Paterson, R L Oakes, M Marmelstein, R. J. Kellett, R. H Pratt, J. Sorett, W Charney, J R M'Elroy

PART II.—M B —*Emily M Booth, D M Mitchell, H D Clarke, M J Horgan, H R. Davies, D M Ahern, W. H E M'Kee, J S M Pringle, E C. Rowlette, Marjorie R E Boyd, H. S Barber, Esther C. L Howe, W. P Griffin, N Jackson, M J Roberts, J S Ruddell, E. S. A. Ashe, J Bell, Ethel S Wilson, Mary J Ahern, G S. S. Harty, J K Lavery, Agnes Monteiro, C W. N. Smiley, E Howitt, Una M Irvine, Eileen M Kennedy, I F F Wiley, J. T M Gregg, A Dolphin

B CH —*D M Mitchell, M. J. Horgan, D M Ahern, Emily M Booth, H D Clarke, H S Barber, H R Davies, Marjorie R E Boyd, Ethel S Wilson, W P Griffin, J K Lavery, W A Clarke, H S Perrot, Eileen M. Kennedy, C W N Smiley, J S Ruddell, M J Roberts, E C Rowlette, W. F. Bermingham, Una M Irvine, H F Ryan

B A O —E E. O'Malley, Mary E Mansfield, Helena G G Bennett, Ethel S. Wilson, Sheila K Henderson, M. H. Cosbie, B E W. Aldwell.

D P H —*Part II (Old Regulations):* Frances E O'Connor (*New Regulations*) · Marjorie L Campbell, E S Duthie, W. E Holmes, C H Adderley, J V. Ryan, A. A Lisney

DIPLOMA IN GYNAECOLOGY AND OBSTETRICS —M. M. El Hennawy, V. Enok

* Passed on high marks

The following prizes have been awarded. *Cunningham Memorial Medal and Prize,* J. H. A. Jewell. *FitzPatrick Scholarship,* D. M. Mitchell. *John Mallet Purser Medal,* E W. L. Thompson. *Medical Scholarship: Physics, Chemistry, Botany, and Zoology,* R. E Taylor , *Anatomy and Physiology,* B E. O'Brien. *Stewart Medical Scholarships: Physics, Chemistry, Botany, and Zoology,* T. L Lawson ; *Anatomy and Physiology,* E W. L Thompson *Medical Travelling Prize and Banks Medal,* J A Wallace *Medical Travelling Prize (special) and Banks Prize,* A. A Cunningham *De Renzy Centenary Prize,* Marjorie L. Campbell. *Aquilla Smith Prize and Walter G Smith Prize,* W. A. Gillespie.

NATIONAL UNIVERSITY OF IRELAND

A meeting of the Senate was held on July 6th, under the chairmanship of the Chancellor, Mr. Eamon de Valera.

The reports of the examiners on the results of the summer examinations were considered, and passes, honours, etc., awarded in connexion therewith

The following appointments in University College, Cork, were made: *Lecturer in Medical Jurisprudence,* M. J. Riordan, M.B , B Ch., M A.O., F.R.C.S I ; *Lecturer in Mental Diseases,* B F. Honan, L R.C.P. and S.I., D.P.M.

A report from Dr. Denis J. Coffey, president, University College, Dublin, and representative of the University on the General Medical Council, was considered and approved

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Election to the Council

On July 6th five Fellows were elected into the Council to fill the vacancies occasioned by the retirement in rotation of Lord Moynihan, Sir John Lynn-Thomas, Mr. A H. Burgess, and Mr. V Warren Low, and by the death of Sir Percy Sargent. The result of the poll was as follows.

	Votes	Plumpers
SIR CHARLES GORDON-WATSON, K B E , C M G (St Bartholomew's)	785	29
ARTHUR HENRY BURGESS (Manchester)	773	12
HENRY SESSIONS SOUTTAR, C B E (London)	579	24
REGINALD CHEYNE ELMSLIE (St Bartholomew's)	553	8
LEONARD RALPH BRAITHWAITE (Leeds)	547	28
Charles Max Page	527	8
Claude Howard Stanley Frankau	444	24
Cyril Alfred Rankin Nitch	439	4
Duncan Campbell Lloyd Fitzwilliams	415	27
Alfred William Sheen	384	3

In all 1,420 Fellows voted, including 253 resident out of Great Britain and Ireland , in addition eight votes were found to be invalid

Mr Braithwaite becomes substitute member of Council for Lord Moynihan until 1935 Mr Elmslie becomes substitute member of Council for the late Sir Percy Sargent until 1938 Sir Charles Gordon-Watson, Mr Burgess and Mr Souttar are elected for the full period of eight years

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting of the College, held on July 7th, the following candidates who had passed the Final Professional Examination under the conjoint scheme with the Royal College of Surgeons in Ireland, were duly admitted Licentiates in medicine and midwifery of the College—namely J S Barr, C N Carroll, T W Conlin, W. P. J. Dunsmore, P W Griffin, T Healy, F. Jupe P J Kelly, R J F Matthews, P J Moore, D McAuliffe Phoebe I McKernan, D E O'Driscoll, P S O'Golain, J T. O'Hanrahan, P V O'Reilly, J J Pierse, H R Rogers, Kathleen M N Vickers, A. E Warren

The Services

BOMBARDMENT OF MEDICAL UNITS

The seventh International Congress of Military Medicine and Pharmacy, held recently in Madrid, considered the constantly increasing dangers of bombardment to which medical units and fixed hospital establishments are likely to be exposed, and adopted the following recommendations (1) That hospital areas be reserved for the exclusive requirements of the medical service and placed under the sign of the Red Cross (2) That regulations be introduced as early as possible to determine the conditions of application of this recommendation in the Geneva Convention for the amelioration of the lot of the sick and wounded in the armies in the field

DEATHS IN THE SERVICES

Major Percy Reginald O'Rourke Phillips, R A M C., died of pneumonia at York Military Hospital on June 15th aged 42 He was born on March 25th, 1891, was educated at Highgate School, at Pembroke College, Cambridge, where he graduated B.A., and at St. Thomas's Hospital and took the M.R.C.S. and L.R C P.Lond. in 1913 He held a temporary commission as lieutenant in the R A M C during the war, on April 28th, 1916, and subsequently a permanent commission from the same date, and attained the rank of major on April 28th, 1928 He served in the war of 1914-18, and, since the war, in the Egyptian Army, and at Shanghai

Lieut.-Colonel John Leopold Poynder Madras Medical Service (ret.), died at Bickington Lodge on June 26th aged 78. He was the son of the Rev Leopold Poynder was born at Bareilly on March 11th, 1855 was educated at Bart's and took the L R C P Lond the M R C S , and the L S A in 1877 Entering the I M S as surgeon on October 31st 1879 he became lieutenant-colonel after twenty years service and retired on December 12th 1909 Most of his service was spent in civil employ in the Central Provinces On June 26th 1902, he received the Kaisar-i-Hind medal first class

Medico-Legal

ALLEGED NEGLIGENCE BY "NATURE-CURER"

Patient's Claim for Damages

Before the Lord Chief Justice and a special jury on July 4th, 5th, and 6th, an action was heard in which Mrs. Eleanor May Walton of New Cavendish Street, W., claimed damages from Mr. Stanley Lief of Park Lane, W., and Natural Healing, Ltd., of Champneys, Wigginton, Herts, for personal injuries alleged to have been caused by the negligence of the defendants and for breach of warranty to cure her of lupus erythematosus. The plaintiff's case was that in February of last year Mr. Lief, who directs and substantially owns the sanatorium at Wigginton, warranted that he was in a position to cure her completely if she undertook his treatment. She remained in his sanatorium for five weeks, and afterwards underwent some further treatment from him at Park Lane, but with the result that her face and scalp became permanently disfigured. She complained that she was improperly treated by radiations, and that the diet given in the sanatorium was insufficient.

Mrs. Walton, in reply to Sir Patrick Hastings, K.C., her counsel, stated that she had suffered from lupus erythematosus since 1921. In 1931 there remained, after treatment at the hands of various doctors, one or two scars on her face, but none on her scalp. Since her treatment by Mr. Lief the disease had extended and covered the whole of her scalp and both sides of her face. She paid twelve guineas a week at the sanatorium. She was kept on a low fruit diet, and never had a real meal during the five weeks of her stay. Light treatment was started after she had been there seventeen days. The last session of light treatment at Park Lane left her in great pain, and patches appeared around the eyes.

Lord Horder stated that he saw the plaintiff in April last. In lupus erythematosus the administration of irritants was to be avoided. Ultra-violet rays were irritating unless applied in very small doses. *X* rays in very small doses might have a healing effect, but the measurement of the dose would require to be made extremely carefully. The plaintiff's was an unfortunate type of case to get into the hands of an inexperienced person. Starvation treatment was a bad preface to any local treatment, as it might make the patient more susceptible to over-stimulation. He was not prepared to agree that one of the fruitful causes of lupus erythematosus was intestinal poisoning, though, of course, the cleansing of the intestinal system was good in all diseases. Lupus erythematosus might flare up without any apparent reason, but his impression was that the application of ultra-violet rays in this case had made the disease active.

Mr. Norman Birkett, K.C., for the defence, said that he proposed to call medical evidence to show that burning by ultra-violet treatment was quite impossible. This disease was one about which medical science knew little; its cause was unknown, and it was not known why it occasionally flared up.

Mr. Stanley Lief, in the witness-box, described himself as an osteopath and naturopath, who had come to this country from America in 1914. He was questioned as to certain initials following his name. "M.N.C.A. meant "Member Nature Cure Association," of which he was president; "D.O." meant "Doctor of Osteopathy," "D.C." "Doctor of Cheiropathy," and "N.D." "Naturopathic Doctor," these three degrees having been conferred by colleges in Chicago. There was an average of sixty-five resident patients at Champneys. When he saw Mrs. Walton he told her that her condition was due to impure blood and intestinal toxaemia, and that it would be well worth while to attempt purification of the system. The question of guaranteeing a cure was never raised. The light treatment was given from a mercury vapour lamp at 30 in. from the face for one minute at first, and later in increasing doses up to eight minutes. When he treated her at Park Lane he used a Kromayer lamp, 1½ in. from the face. In cross-examination he said that Natural Healing, Ltd., the defendant company, had about a dozen shareholders; he owned more than half the shares. A newspaper, *Health for All*, was the property of the company. It was suggested to him that in this periodical it was stated that no disease was incurable at Champneys, to which Mr. Lief replied that cancer, tuberculosis, and paralysis were excepted.

Evidence in support of the defendant's case was given by Mr. Sidney Alfred Cullum, osteopath, formerly Mr. Lief's assistant, who said that the plaintiff made good progress while at Champneys, and by Dr. William Kerr Russell and Mr. J. E. R. McDonagh, F.R.C.S., the latter stating that the disease from which the plaintiff suffered might be beneficially treated by ultra-violet rays, though he would not himself now use that treatment because other treatment would achieve better results. The disease had a tendency to flare up for undiscoverable reasons, though he did not think ultra-violet rays would cause it to do so. He would not have advised starvation diet for a month.

The jury were absent for more than three hours considering their verdict. They found for the plaintiff on the question of representation and warrant that the defendant was in a position to effect a complete cure of the plaintiff's disease, and assessed damages at the amount of the bill—namely, £123 16s. They also found for the plaintiff on the question of negligence in treatment, and awarded one farthing damages. They added the rider that all institutions of this character should be subject to supervision by some Government authority. Judgement was entered for plaintiff accordingly, and the question of costs reserved for future argument.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons has this week discussed the Estimates for Education, Agriculture, the Colonies, and the Foreign Office. On the last a debate arose on the World Economic Conference. The Samaritan Free Hospital Bill, which has passed the House of Lords, was read a second time by the House of Commons on July 10th. The committee stage of the Road and Rail Traffic Bill was completed in Standing Committee.

The Nurses Registration Act (1919) Amendment Bill, the Registration and Regulation of Osteopaths Bill, and the Shops Act (Amendment) Bill have been withdrawn.

In the House of Lords the University Degrees Bill was put down for second reading on July 13th, and the Manchester Royal Infirmary Bill for committee on the same date. The Local Government and Other Officers Superannuation (Temporary Provisions) Bill received a first reading on July 6th. The Cancer Hospital (Free) Bill was returned to the Commons, and the Road Traffic (Compensation for Accidents) Bill was reported from a committee and put down for consideration by the House on July 18th. On July 11th the Earl of Lucan presented the Firearms and Imitation Firearms (Criminal Use) Bill, which was read the first time.

On July 6th, after a division, the House of Commons approved the special grant of £440,000 to local authorities in England and Wales for out-relief expenditure. In moving the grant Sir HILTON YOUNG said a permanent scheme of relief for these authorities would be introduced in the present session.

Administration and Cost of Health Services

On July 7th Sir HILTON YOUNG presented the estimates of the Ministry of Health for the year ending March 31st, 1934. He said that, disregarding the vote of £39,000,000 for block grants to local authorities, the actual Vote of his Department was £19,000,000, a decrease of £135,800. An increase of £250,000 in housing grants was offset by a decrease of £375,000 on the Health Insurance Vote. In 1932 £120,000 had to be voted for the influenza epidemic. That epidemic had not returned, and the expenditure was not required this year. The administration of the Department showed a decrease of £2,800, although the staff of the Ministry was increasing on account of the constantly expanding health services. In administration of health services

the measures taken to ensure the future were the most important part of the work He instanced the difficult question of the sterilization of the unfit The expense of the mental deficiency service was enormous, and the disadvantage of mental deficiency to national life still graver Another example of work in which they were looking ahead was the setting up of a new consultative committee of the twenty eight London borough councils and the City Corporation to co ordinate their interests with those of the localities where the London refuse dumps were situated Another concerned the standards of construction in the public institutions of large cities, such as hospitals, workhouses, mental homes, and so on It was necessary for efficiency and economy that there should be some normal standards for the construction of these buildings, and he had started an inquiry which would establish the standards and provide permanent machinery for keeping them up to date To the actual work of town and country planning the Act passed last year had given a great impetus, and the Department was now ready to proceed without delay with any scheme which came along The end of the epoch of general subsidies for housing had been accompanied by increased activity in the building trade There had been practically no drop in the production of houses during the transition to the period of private enterprise The number of houses approved in the first five months of 1933 was 17 800, a little more than in the first five months of 1932 For the twelve months to April 1st, 1933, 200 500 houses, assisted and unassisted, had been produced Local authorities were making plans for a five year campaign against slums, and had been asked to produce these plans before the end of September Stoke on Trent, which had recently cleared houses at the rate of eighteen a year, now had a scheme to clear 3 612 houses, at the rate of 720 a year A Minister of Health must be alert for symptoms that the long depression was beginning to tell on the health of the country The result of a widespread inquiry showed that unemployment and insecurity of employment particularly in the case of the young undoubtedly told on the mental health On the physical health of the nation he could give a different account For information on nutrition the Ministry of Health had the school medical officers the medical officers of health and the regional medical officers in connexion with the health services, the inspectors of the Ministry, and, lastly, the statistics of mortality and morbidity The mortality for the whole country and for the depressed areas was steadily declining, which testified to the maintenance of the general health of the people There was an encouraging decrease *in the death rate among children* Since 1910 the infant mortality rate had been halved—a marvellous achievement for the new welfare services and the medical profession He found no evidence of increased morbidity in the country as a whole Morbidity statistics for pneumonia and bronchitis were going down In tuberculosis—most important as a barometer of health and nutrition—the death rate per million for all forms fell from 896 in 1931 to 838 in 1932 Owing to the success of the health services for children there was a marked fall in the incidence and mortality of non pulmonary tuberculosis The statistics for maternal mortality were *matter for dissatisfaction* This mortality was due to particular diseases and disorders at the time of the birth The mortality last year was 4 11, and this year 4 21 To deal with this question better education of the mother and of the midwife was necessary The Ministry constantly pressed local authorities to raise the standard of the maternity services The number of infant welfare centres was increasing and ante natal centres were conspicuously increasing He had seen the reports of medical officers of health and regional medical officers on the actual state of the physical health of the country *and of the unemployed, with special* relation to malnutrition The health of the country was normal in spite of the depression Sir Hilton advised local authorities when looking for malnutrition in a family, to look at the woman At such times as these there was a special responsibility for watching the health of the mothers of the country In these bad times the public medical services for the insured, for maternity, for infant welfare for the school child, for general and special nursing and health visitation and for the treatment of special diseases such as tuberculosis proved of inestimable service to the country Turning to economy Sir Hilton Young said local authorities had carefully surveyed the objects of outlay and the efficiency of the services and this had resulted in useful and important economies without sacrifice of efficiency

Opposition Criticism

Mr GREENWOOD approved what the Minister said about the measures taken for hospitals and for town and country planning but he thought there should have been a larger output of houses Concerning nutrition the House should consider the economic facts A report by the Sheffield Social Committee Council showed that one fifth of the working class households in Sheffield were living below or on the poverty line, with resources insufficient to cover minimum requirements in respect of rent, food clothing heat light, and household utensils In course of time the shortage of the necessities of life would show sorry results although not now reflected in the morbidity rate or the death rate Figures given by Sir George Newman on the health of the school child showed an incidence of malnutrition per 1 000 inspections of 9 5 in 1925, 10 6 in 1930 and 11 2 in 1931

Medical Benefit and the Unemployed

Mr DINGLE FOOT said the Ministry of Health should now be ready to meet the difficulties at the end of this year when persons who had been unemployed for two and a half to three years would lose their entitlement to medical benefit Many of these persons—he believed they numbered about 100,000—would continue to go for treatment to the panel doctors they had been consulting These doctors would be in a difficult position The change would simply transfer the burden from national to local shoulders Instead *of the cost of medical treatment for these people being* borne on national health insurance funds it would be borne by public assistance funds, and the principal burden would fall on the distressed areas He suggested that there should be a transitional class for health insurance as for unemployment insurance Mr TINKER suggested that besides preventing the growth of refuse dumps round London the Minister should bring about the removal of the chemical heaps round Widnes and St Helens and the colliery dumps of mining areas, the fumes from whose spontaneous combustion were often almost unbearable

Mr BUCHANAN suggested that part *of the national health* insurance reserve fund should be used to keep within insurance those who would otherwise pass out of it To tell such persons that they must have recourse to the Poor Law for a doctor would be forcing them to go to practitioners in whom they had no faith In many cases doctors who had been associated with a man or a man's family for a long time would do the work for nothing, but it was not fair that members of the medical profession should be asked to undertake a national burden as an individual one No hardship would be done to any approved society which used a proportion of its surplus to keep these people within the insurance limit

Hospital Co operation

Sir FRANCIS FREMANTLE said that the great mass of houses which were now going up were not of the low rental type *which would meet the needs of the poorer paid workers* He hoped the Government could say something on the prospect of a report from the committee which, with Lord Marley as its chairman, was inquiring into the future development of existing towns, or the development of new towns in the form of garden cities He agreed with the contention of previous speakers that it was a mistake if persons having exhausted certain rights under the national health insurance had to leave a panel doctor and go to a Poor Law doctor Why the distinction between the panel and the Poor Law when both were administered by one Department Was it *not possible to fuse the schemes for the provision* of medical benefit whether under insurance or public assistance? From the professional point of view it would be infinitely better to have a system under which one medical man would look after all the members of a family They could then decide whether he should be paid from the Insurance Fund or from some other fund Sir Francis asked if there was any [illegible] of the co operation which was promised under the Local Government Act of 1929 between the voluntary hospitals and hospitals under local authorities Rumours reached [illegible] that the co operation between the larger voluntary [illegible] of London and the London County Council was [illegible]

than nominal. He hoped the Ministry of Health would bring pressure to bear on those places where co-operation had not been brought about. At one of the smaller hospitals near London he found a scheme under which two of the hospital nurses were engaged in district nursing for the whole district. They dealt with out-patients at the hospital, followed up the cases, and also did the ordinary work of district nurses. The result was a great saving. He hoped the Department would see how far this idea could be pressed forward. The time had come for co-ordination between the voluntary hospitals and the district nursing movement, especially under the Queen's Institute. Co-ordination was required between the nurses' pensions schemes of local authorities and of the voluntary hospitals. The subject would be brought forward by those who represented the nursing profession. A further opportunity for co-ordinating and fusing the health services came under the Local Government Act, 1929. Why should the same local authority have different sets of officials to manage different branches of the health services? The education clinic, the hospital services, the tuberculosis service, were watertight compartments, each under a different committee, with practically independent officers and organization. The Minister would have to appoint a further committee with a view to a closer fusion of services under the same local authorities. A special investigation was required, going right back to what were the real requirements in the training and education of the medical services. The Minister should urge upon the General Medical Council, through his own representative, the fact that in training attention was still directed too much to the production of practitioners for the treatment of disease and not nearly enough to the training of medical men in the prevention of disease.
